ORIGIN, SCOPE, AND PLAN,
OF THE
ROTHAMSTED EXPERIMENTS.⁽¹⁾

MR. (afterwards SIR) JOHN BENNET LAWES was the founder of the Rothamsted Experimental Station. He commenced experiments with different manuring substances, first with plants in pots, and afterwards in the field, soon after entering into possession of his hereditary property at Rothamsted² in 1834. The researches of De Saussure on vegetation were the chief subjects of his study to this end. Of all the experiments so made, those in which the neutral phosphate of lime, in bones, bone-ash, and apatite, was rendered soluble by means of sulphuric acid, and the mixture applied for root-crops, gave the most striking results. The results obtained on a small scale in 1837, 1838, and 1839, were such as to lead to more extensive trials in the field in 1840 and 1841, and subsequently.

In 1843, more systematic field experiments were commenced; and a barn, which had previously been partially applied to laboratory purposes, became almost exclusively devoted to agricultural investigations. The foundation of the Rothamsted Experimental Station may be said to date from that time (1843).

The Rothamsted station has from the commencement been entirely disconnected from any external organization, and has been maintained entirely at the cost of the late Sir John Lawes. It had in previous years been stated, that he had further set apart a sum of £100,000, the Laboratory, and certain areas of land, for the continuance of the investigations after his death. In February 1889, Trustees were appointed, and the necessary Trust Deed was executed; and, in accordance with the provisions of the Deed, a Committee of Management was soon afterwards appointed, and entered upon its duties.

(¹) The statement of the origin, scope, and plan, of the Rothamsted Investigations, was originally drawn up in answer to a circular letter issued by a Committee appointed to arrange for the commemoration of the twenty-fifth anniversary of the establishment of the First Experimental Station in Germany (Möckern), which was held in Leipzig in September 1877. The precise form of the statement depended on the order and form of the questions to which it was an answer. It was published in German, almost in full, with the series of reports of other Experimental Stations, which was issued at the time of the Jubilee Meeting. (*Die landwirthschaftlichen Versuchs-Stationen. Band xxii. 1877.*) To the general statement, which is annually given in the form in which it was originally drawn up, but which is each year corrected up to date, are appended lists of the titles of all the papers already published, with full reference to the Journals in which they appeared.

(²) Rothamsted is in Hertfordshire, twenty-five miles from London, on the Midland Railway; Station, Harpenden. Postal address—Harpenden, St. Albans. Telegraphic address—Harpenden.

N.B.—It is requested that those wishing to inspect the experiments will give notice, either by letter or telegram, to Sir J. Henry Gilbert, as to the time of their intended visit.

The Trustees are :—

Lord AVEBURY, F.R.S.

Sir JOHN EVANS, K.C.B., F.R.S. | LORD WALSHINGHAM, F.R.S.

The Committee consists of nine Members :—

Sir JOHN EVANS, K.C.B., F.R.S. (Chairman)	} Nominated by :— The Royal Society.	
Dr. HUGO MÜLLER, F.R.S. (Treasurer)		
Sir MICHAEL FOSTER, K.C.B., M.P., Sec. R.S.		
Dr. HORACE T. BROWN, F.R.S.		
Professor H. E. ARMSTRONG, LL.D., F.R.S.		
WILLIAM CARRUTHERS, Esq., F.R.S.	} The Chemical Society.	
Sir JOHN H. THOROLD, Bart., LL.D.		} The Linnean Society.
Dr. JOHN A. VOELCKER, M.A.		
And Sir CHARLES B. LAWES, Bart.	} The Royal Agricultural Society of England.	

From June 1843, up to the time of Sir John Bennet Lawes' death in August 1900, Dr. (now Sir) J. Henry Gilbert was associated with him in the conduct of the experiments, and has had the direction of the laboratory.

In 1854-5 a new laboratory was built, by public subscription of agriculturists, and was presented to Sir John Lawes in July 1855, from which date the old barn-laboratory was abandoned, and the new one has been occupied.

The number of assistants and other helps has increased from time to time. At first only one laboratory man was employed; but very soon a chemical assistant was necessary, and next a computer and record-keeper.

For many years the staff has consisted of—

One or two, and sometimes three, chemists.

Two or three general assistants. One of these is usually employed in routine chemical work, but sometimes in more general work. The chief occupation of the general assistants is to superintend the field experiments—that is, the weighing and mixing of the manures, the measurement of the plots, the application of the manures, and the harvesting of the crops; also, the taking of samples, the preparation of them for preservation or analysis, and the determinations of dry matter, ash, &c. These assistants also keep the meteorological records, and superintend any experiments made with animals.

A botanical assistant has also occasionally been employed, with from three to six boys under him; and with him has been associated one of the permanent general assistants, who at other times undertakes the botanical work.

Two or three (and sometimes four) computers and record-keepers have been occupied in calculating and tabulating field, feeding, and laboratory results, copying, &c.

A laboratory man, and other helps, are also employed.

Besides the permanent laboratory staff, chemical assistance has frequently been engaged in London, or elsewhere. In this way, Mr. R. Richter, now of Charlottenburg (Berlin), but who was for some years in the Rothamsted Laboratory, has executed much analytical work sent from Rothamsted. He has, in fact, here and at Charlottenburg, made about 900 complete analyses of the ashes of various products, animal and vegetable, of known history.

The field experiments, and occasionally feeding experiments, also employ a considerable but a very variable number of agricultural labourers.

There is now a collection of about 50,000 bottles of samples of experimentally-grown vegetable produce, of animal products, of ashes, or of soils, besides some thousands of samples not in bottles; and, the Laboratory having become very inconveniently full, a new detached building—a "Sample House"—was erected in the autumn of 1888, comprising two large rooms for the storing of specimens, and for some processes of preparation, and also a drying room. The Laboratory, where a very large number of specimens, and the records, will still be kept, is thus relieved of the heavier, the more bulky, and the more combustible, of its former contents, and also of the risk of fire from stove-drying.

Nothing has been done at Rothamsted in the way of manure, feeding-stuff, or seed-control.

The investigations may be classed under two heads :—

(5)

I.—FIELD EXPERIMENTS, EXPERIMENTS ON VEGETATION, ETC.

The general scope and plan of the field experiments has been :—

To grow some of the most important crops of rotation, each separately, year after year, for many years in succession on the same land, without manure, with farmyard-manure, and with a great variety of chemical manures; the same description of manure being, as a rule, applied year after year on the same plot. Experiments on an actual course of rotation, without manure, and with different manures, have also been made. In this way field experiments have been conducted for the periods, and over the areas, indicated in the following Table :—

CROPS.	Duration.	Area.	Plots.
	Years.	Acres.	
Wheat (various manures)	58	11	34 (or 37) ⁽¹⁾
Wheat, alternated with Fallow	50	1	2
Wheat (varieties)	15	4-8	about 20
Barley (various manures)	50	4½	29
Oats (various manures)	10 ⁽¹⁾	0½	6
Beans (various manures)	32 ⁽²⁾	1½	10
Beans (various manures)	27 ⁽³⁾	1	5
Beans, alternated with Wheat	28 ⁽⁴⁾	1	10
Clover (various manures)	29 ⁽⁵⁾	3	18
Various Leguminous Plants	24	3 ⁽⁶⁾	18 ⁽⁶⁾
Turnips (various manures)	28 ⁽⁶⁾	8	40
Sugar Beet (various manures)	5	8	41
Mangel-Wurzel (various manures) ..	26	8	41
Total Root Crops	59		
Potatoes (various manures)	26	2	10
Rotation (various manures)	54	3	12
Permanent Grass (various manures)	46	7	22

⁽¹⁾ Including 1 year Fallow.

⁽²⁾ Including 1 year Wheat, and 5 years Fallow.

⁽³⁾ Including 4 years Fallow.

⁽⁴⁾ Including 2 years Fallow.

⁽⁵⁾ Clover, 12 times sown (first in 1848), 8 yielding crops, but 4 of these very small, 1 year Wheat, 5 years Barley, 12 years Fallow.

⁽⁶⁾ Including Barley without Manure 3 years (11th, 12th, and 13th seasons).

⁽⁷⁾ Reduced to 19 plots in 1894 and since (see plan, p. 28, also description, p. 31).

⁽⁸⁾ Reduced in 1898 to 5ths of an acre, and to 5 plots.

Comparative experiments with different manures have also been made on other descriptions of soil, in other localities.

Samples of all the experimental crops are taken, and brought to the laboratory. Weighed portions of each are partially dried, and preserved for future reference or analysis. Duplicate weighed portions of each are dried at 100° C., the dry matter is determined, and it is then burnt to ash on platinum sheets, in cast-iron muffles. The quantities of ash are determined and recorded, and the ashes themselves are preserved for reference, or analysis.

In a large proportion of the samples the nitrogen is determined; and in some the amount existing as albuminoids, amides, and nitric acid.

In selected cases, illustrating the influence of season, manures, exhaustion, &c., complete ash-analyses have been made, numbering in all more than 800.

Also in selected cases, illustrating the influence of season and manuring, quantities of the experimentally-grown Wheat grain have been sent to the mill, and the proportion and composition of the different mill-products determined.

In the Sugar Beet, Mangel-Wurzel, and Potatoes, the sugar has in many cases been determined by polariscope, and frequently by copper also.

In the case of the experiments on the Mixed Herbage of Permanent Grass-land, besides the samples taken for the determination of the chemical composition (dry matter, ash, nitrogen,

woody fibre, fatty matter, and composition of ash), carefully averaged samples have frequently been taken for the determination of the botanical composition. In this way, on four occasions, at intervals of five years—viz., in 1862, 1867, 1872, and 1877—a sample of the produce of each plot was taken, and submitted to careful botanical separation, and the percentage, by weight, of each species in the mixed herbage determined. Partial separations, in the case of samples from selected plots (frequently of both first and second crops), have also been made in many other years.

INVESTIGATION OF SOILS.

Samples of the soils of most of the experimental plots have been taken from time to time, generally to the depth of 9, 18, and 27 inches, sometimes to twice, and sometimes, for special purposes, to even four times this depth; samples being taken at two, or sometimes even at eight places, on the same plot. In this way more than 4200 individual samples have been taken; but sometimes those of corresponding depth from the different places on the same plot, have been at once mixed, so that the number for analysis has thus been reduced by about two-fifths. The individual or mixed samples are submitted to partial mechanical separation; generally some further mixtures are then made; and weighed portions (frequently several), of the individual or mixed sifted soils, are carefully preserved for analysis. In a large number of samples the loss on drying at different temperatures, and at ignition, has been determined. In most the nitrogen has been determined, in many by the soda-lime method, but in recent years the Kjeldahl method has also been used. In many the carbon, and in many the nitrogen as nitric acid, and the chlorine, have been determined. Some experiments have also been made on the comparative absorptive capacity (for water and ammonia) of the different soils and subsoils. The systematic investigation of the amount, and the condition, of the nitrogen, and of some of the more important mineral constituents, of the soils of the different plots, and from different depths, has been undertaken, and is from time to time recurred to. The results of the numerous investigations of the Rothamsted soils were last year brought together, and were, under the auspices of the Lawes Agricultural Trust Committee, made the subject of a series of lectures by Dr. Bernard Dyer, which he delivered at the Convention of the Association of American Agricultural Colleges and Experiment Stations, held at New Haven, Conn., U.S.A., in November 1900. It is hoped that the lectures, including the whole of the results in question, will be published by the United States Department of Agriculture in the course of the present year.

RAINFALL AND DRAINAGE.

Almost from the commencement of the field experiments the rainfall has been measured, for more than forty-eight years in a gauge of one-thousandth of an acre area, as well as in an ordinary small funnel-gauge of 5 inches diameter. An 8-inch "Board of Trade" copper gauge has also been in use since January 1, 1881. The nitrogen, as ammonia and as nitric acid, has periodically, and for some years past monthly, been determined in the rain waters. The chlorine has been determined in a considerable series of samples; and sometimes the sulphuric acid also.

Three "drain-gauges," also each of one-thousandth of an acre area, for the determination of the quantity and composition of the water percolating respectively through 20 inches, 40 inches, and 60 inches depth of soil (with its subsoil in natural state of consolidation) were constructed in 1870. A more numerous series of smaller "drain-gauges," arranged for the investigation of the influence of different crops, and of different manures, on the amount and composition of the drainage waters, were constructed in 1874; but they proved not to be water-tight, and have therefore not been used.

Each of the differently manured plots of the permanent experimental Wheat-field having a separate pipe-drain, samples of the drainage waters have been, and are still, collected and analysed. For the purpose of collection, an open pit was, in 1866, dug at the point of junction of each individual plot-drain with the main cross-drain, and the connection broken. The collection-pits were, however, 22 yards further from the manure- and crop-line of the

plots at one side of the field than at the other. During the spring of 1896, a brick trench, 434 feet long, and nearly 3 feet wide and deep, was constructed, at a uniform distance from the manure- and crop-line of all the plots, into which the plot-drain of each was brought; a length of cement-jointed glazed piping being substituted for the "horse-shoe and sole" drains, up to within 6 feet of the manure- and crop-line, thus equalising and lessening the distance that the unjointed drains run under unmanured and uncropped land subject to the passage downwards of surface-water. This arrangement for the better collection of the drainage water from the experimental plots has already been found to be a great improvement; and it will doubtless prove of much value in the future.

More than 25 years ago, Professor Frankland determined the nitrogen, as ammonia, as nitric acid, and as organic nitrogen, and also some other constituents, in many samples both of the rain and of the various drainage-waters collected at Rothamsted. The late Dr. Voelcker also determined the combined nitrogen, and likewise the incombustible constituents, in sixty-five samples of the drainage-waters. And Dr. W. J. Russell has determined the sulphuric acid in some of the monthly mixed samples of rain-water.

The nitrogen existing as nitric acid, sometimes that in other forms, and also some other constituents, are, and for some time past have been, determined periodically, in the Rothamsted Laboratory, in both the rain and the various drainage waters.

AMOUNT OF WATER TRANSPIRED BY PLANTS.

Commencing in 1849, experiments were made, for ten years in succession, to determine the amount of water given off by plants during their growth. In this way various plants, including representatives of the gramineous, the leguminous, and other Orders, were experimented upon. Similar experiments were also made with various evergreen and deciduous trees.

BOTANICAL CHARACTERISTICS, &c.

Having regard to the difference in the character and amount of the constituents assimilated by plants of different botanical relationships, under equal external conditions, or by the same description of plants, under varying conditions, observations have been made on the character and range of the roots of different plants, and on their relative development of stem, leaf, &c. In the case of various crops, but more especially with Wheat and Beans, samples have been taken at different stages of growth, and the composition determined, in more or less detail, sometimes of the entire plant, and sometimes of the separated parts. In a few cases, the amounts of dry matter, ash, nitrogen, &c., in the above-ground growth of a given area, at different stages of development, have been determined. The amounts of stubble of different crops have also occasionally been estimated. Experiments have also been made to ascertain approximately the acidity of the root-sap of a large number of plants representing various Natural Orders.

EXPERIMENTS ON THE ASSIMILATION OF FREE NITROGEN.

Experiments were commenced in 1857, and conducted for several years in succession, to determine whether plants assimilate free or uncombined nitrogen, and also various collateral points. Plants of the gramineous, the leguminous, and of other families, were operated upon. The late Dr. Pugh took a prominent part in this inquiry. The conclusion arrived at was that our agricultural plants do not themselves directly assimilate the free nitrogen of the air by their leaves.

In recent years, however, the question has assumed quite a new aspect. It now is—whether the free nitrogen of the atmosphere is brought into combination under the influence of micro-organisms, or other low forms, either within the soil, or in symbiosis with a higher plant, thus serving indirectly as a source of nitrogen to plants of a higher order. Considering that the results of Hellriegel and Wilfarth on this point were, if confirmed, of great significance and importance, it was decided to make experiments at Rothamsted on somewhat similar lines. Accordingly, a preliminary series was undertaken in 1888; more extended series were conducted in 1889, and in 1890; and the investigation was continued up to the commencement

of the year 1895. Further experiments relating to certain aspects of the subject were commenced in 1898, and are still in progress. The results have shown that, when a soil growing leguminous plants is infected with appropriate organisms, there is a development of the so-called leguminous nodules on the roots of the plants, and, coincidentally, increased growth and gain of nitrogen. The subject is further referred to at pp. 37 and 48 *et seq.*

II.—EXPERIMENTS ON ANIMALS, ETC.

Experiments with the animals of the farm were commenced early in 1847, and have been continued, at intervals, nearly up to the present time.

The following points have been investigated :—

1. The amount of food, and of its several constituents, consumed in relation to a given live-weight of animal within a given time.
2. The amount of food, and of its several constituents, consumed to produce a given amount of increase in live-weight.
3. The proportion, and relative development, of the different organs or parts of different animals.
4. The proximate and ultimate composition of the animals in different conditions as to age and fatness, and the probable composition of their increase in live-weight during the fattening process.
5. The composition of the solid and liquid excreta (the manure) in relation to that of the food consumed.
6. The loss or expenditure of constituents by respiration and the cutaneous exhalations—that is, in the mere sustenance of the living meat-and-manure-making machine.
7. The yield of milk in relation to the food consumed to produce it; and the influence of different descriptions of food, on the quantity, and on the composition, of the milk.

The general plan of experimenting was as follows :—

To provide data as to the amount of food, or its several constituents, consumed in relation to a given live-weight of animal within a given time, and to produce a given amount of increase in live-weight, several hundred animals—oxen, sheep, and pigs—have been experimented upon. Selected lots of animals were supplied, for many weeks, or for months consecutively, with weighed quantities of foods, selected and allotted according to the special point under inquiry. The composition of the foods was determined by analysis. The weights of the animals were taken at the commencement, at intervals during the progress, and at the conclusion of the experiment.

The amount, and relative development, of the different organs and parts were determined in 2 calves, 2 heifers, 14 bullocks, 1 lamb, 249 sheep, and 59 pigs.

The percentages of water, mineral matter, fat, and nitrogenous substance, were determined in certain separated parts, and in the entire bodies, of ten animals—namely, one calf, two oxen, one lamb, four sheep, and two pigs. Complete analyses of the ashes, respectively, of the entire carcasses, of the mixed internal and other “offal” parts, and of the entire bodies, of each of these ten animals, have also been made.

From the data provided, as just described, as to the chemical composition of the different descriptions of animal, in different conditions as to age and fatness, the composition of the increase whilst fattening, and the relation of the constituents stored up in increase to those consumed in food, have been estimated.

To ascertain the composition of the manure in relation to that of the food consumed, oxen, sheep, and pigs, have been experimented upon.

In the case of oxen, the food and litter (sometimes with an acid absorbent), were weighed, sampled, and analysed; the animals were fed in boxes, for periods of from five to nine weeks, and the total dung produced was well mixed, weighed, sampled, and analysed. The constituents

determined in the food and litter on the one hand, and in the dung on the other, were dry matter, ash, and nitrogen.

In the case of sheep no litter was used; the animals were kept in lots of five, on rafters, through which (but with some little loss) the solid and liquid excreta passed on to a sheet-zinc flooring at such an incline that the liquid drained off at once into carboys containing acid, and the solid matter was removed two or three times daily, and also mixed with acid. The constituents determined in the food and manure were dry matter, mineral matter, sometimes woody-fibre, and nitrogen.

In the case of pigs, individual male animals were experimented upon, each for periods of three, five, or ten days only. Each animal was kept in a frame, preventing it from turning round, and having a zinc bottom, with an outlet for the liquid to run into a bottle, and it was watched night and day, and the voidings carefully collected as soon as passed, which could easily be done, as the animal never passed either fæces or urine without getting up, and in getting up he rang a bell, and so attracted the notice of the attendant. The constituents determined were, in the food and fæces, dry matter, ash, and nitrogen, and in the urine, dry matter, ash, nitrogen, and urea.

The loss or expenditure of constituents, by respiration and the cutaneous exhalations has not been determined directly, that is, by means of a respiration-apparatus, but only by difference, that is, by calculation, founded on the amounts of dry matter, ash, and nitrogen in the food, and in the (increase) fæces, and urine.

Independently of the points of inquiry above enumerated, the results obtained have supplied data for the consideration of the following questions:—

1. The sources in the food of the fat produced in the animal body.
2. The characteristic demands of the animal body (for nitrogenous or non-nitrogenous constituents of food) in the exercise of muscular power.
3. The comparative characters of animal and vegetable food in human dietaries.

SUPPLEMENTARY INVESTIGATIONS.

In conjunction with the late Professor Way, an extensive investigation was undertaken on the application of town sewage to different crops, but especially to grass. The amount, and the composition, of both the sewage and the produce grown were determined; and, in selected cases, the composition of the land drainage-water was also determined. Comparative experiments were also made on the feeding qualities of the differently grown produce; the amount of increase yielded by oxen, and the amount and composition of the milk yielded by cows, being determined. In this inquiry part of the analytical work was performed at Rothamsted, but most of it by Professor Way in London.

The chemistry of the malting process, the loss of food constituents during its progress, and the comparative feeding value of barley and malt, have been investigated.

Experiments were commenced in 1884, and continued for several years, to determine the changes and losses which food-crops undergo in the process of ensilaging. Experiments have also been made to determine the comparative value as food—of red-clover-silage as against red-clover-hay-chaff and swedes, when given (with other foods), to fattening oxen; of red-clover-silage, and meadow-grass-silage, as against mangels, when given (with other foods) to milking cows; of silaged green oats, against oats (grain and straw) allowed to ripen, given (with other foods) to fattening oxen; and of meadow-grass-silage, as against corresponding meadow-grass-hay, given (with other foods) to fattening oxen.

A mixed crop of beans, peas, tares, and oats, was silaged in 1886, 1887, and in 1888, and the changes and losses determined by weight and analysis, but the silage was not fed experimentally. A similar mixed crop was sown in June 1889; but it failed, and was ploughed up.

Although many of the results of the investigations above enumerated have already been published, a large proportion as yet remains unpublished.

The following lists give the titles of the papers already published, arranged in two Series, and within each Series arranged in chronological order; and they show in what Journal each paper appeared.

SERIES I.—REPORTS OF FIELD EXPERIMENTS, EXPERIMENTS ON
VEGETATION, &c.

PUBLISHED 1847—1900, INCLUSIVE.

1. Agricultural Chemistry (Jour. Roy. Ag. Soc. Eng., vol. viii., p. 226) 1847
2. Agricultural Chemistry, Turnip Culture (Jour. Roy. Ag. Soc. Eng., vol. viii., p. 494) 1847
3. Experimental Investigation into the Amount of Water Given Off by Plants during their Growth, especially in relation to the Fixation and Source of their various Constituents (Jour. Hort. Soc. Lond., vol. v., p. 38) 1850
4. Report of some Experiments undertaken at the suggestion of Professor Lindley, to ascertain the Comparative Evaporating Properties of Evergreen and Deciduous Trees (Jour. Hort. Soc. Lond., vol. vi., p. 227) 1851
5. Agricultural Chemistry, especially in relation to the Mineral Theory of Baron Liebig (Jour. Roy. Ag. Soc. Eng., vol. xii., p. 1) 1851
6. On the Amounts of, and Methods of Estimating, Ammonia and Nitric Acid in Rain-water (Report of the British Association for the Advancement of Science for 1854—Liverpool Meeting) 1854
7. Report to the Right Hon. the Earl of Leicester, on the Experiments, conducted by Mr. Keary, on the Growth of Wheat upon the same land for four successive years, at Holkham Park Farm (Jour. Roy. Ag. Soc. Eng., vol. xvi., p. 207) 1855
8. On some points connected with Agricultural Chemistry; being a reply to Baron Liebig's "Principles of Agricultural Chemistry" (Jour. Roy. Ag. Soc. Eng., vol. xvi., p. 411) 1855
9. On the Growth of Wheat by the Lois Weedon System, on the Rothamsted Soil; and on the Combined Nitrogen in Soils (Jour. Roy. Ag. Soc. Eng., vol. xvii., p. 582) 1856
10. On some points in the Composition of Wheat Grain, its Products in the Mill, and Bread (Journal of the Chemical Society of London, vol. x., p. 1) 1857
11. On the Growth of Barley by Different Manures continuously on the Same Land; and on the Position of the Crop in Rotation (Jour. Roy. Ag. Soc. Eng., vol. xviii., p. 454) 1857
12. Report of Experiments with different Manures on Permanent Meadow Land, with Tabular Appendix (Jour. Roy. Ag. Soc. Eng., vols. xix., p. 552, and xx., pp. 228 and 398) 1858-9

THE ROTHAMSTED RAIN GAUGES.

N^o 4.

N^o 2

N^o 1.

N^o 3

VIEW SHOWING THE COLLECTORS.

No. 1.—Small Funnel-gauge, 5 inches diameter.

No. 2.—Small Funnel-gauge, 8 inches diameter.

No. 3.—Large Gauge—

Size—7 feet 3·12 in. × 6 feet.

Area—One thousandth of an acre.

4 collectors, each holding Rain = 0·500 in.

Gauge-tubes graduated to .. 0·002 in.

Overflow tank to hold Rain = 2·000 ins.

Small cylinder, tube graduated to 0·001 in.

(For quantities less than 0·05 in.)

No. 4.—Stand with level marble top, for measuring.

THE ROTHAMSTED DRAIN GAUGES.

VIEW.

3 Drain Gauges—

Each 7 feet 3·12 in. × 6 feet = $\frac{1}{1000}$ th acre area :

Respectively 20, 40, and 60 inches depth of soil.

2 collectors, each holding Drainage = 0·500 in.

Gauge-tubes graduated to .. 0·002 in.

Overflow tank to hold Drainage .. = 2·000 ins.

GENERAL SUMMARY OF THE RESULTS RELATING TO RAINFALL
AND DRAINAGE AT ROTHAMSTED.

As already explained (p. 6), the Rainfall has been measured at Rothamsted, in gauges of different sizes almost from the commencement of the Field Experiments; and the Drainage through 20 inches, 40 inches, and 60 inches, of unmanured and uncropped soil, in its natural state of consolidation, has been collected from September 1870, up to the present time, a period of nearly 31 Harvest-years. The nitrogen as nitric acid in the drainage waters was determined occasionally during the first 7 years of their collection (1870-1 to 1876-7); but from 1877-8 up to the present time, a period of nearly 24 Harvest-years, it has been determined in proportional samples for each month. A summary of the numerical results relating to rainfall, drainage, and loss of nitrogen by the drainage, will be found in the Tables at pp. 18-19.

The figures show that over the 20 Harvest-years, 1877-8 to 1896-7, there was an average annual loss of nitrogen in the drainage, of 35·07 lbs. through 20 inches, 30·83 lbs. through 40 inches, and 33·87 lbs. through 60 inches depth, of unmanured and uncropped soil; or, taking the average of the three gauges, of about 33 lb. per acre per annum of nitrogen, corresponding to an average annual loss of nearly 2 cwt. of nitrate of soda.

With reference to the large amounts of loss of nitrogen by the drainage thus indicated, it is to be borne in mind, that probably not more than an average of about 5 lbs. would be contributed annually per acre from the atmosphere in rain and the minor aqueous deposits, exclusive of any condensation by the soil. Moreover, the soil of the drain-gauges had been unmanured since 1868; but, being exposed to the access of air from below as well as from above, the oxidation of the nitrogenous matters of the soil and subsoil may be more active than in similar soil in its natural condition. On the other hand, the soil was without any vegetation to arrest the nitric acid formed; whilst, in some cases of fallow-land which had been manured and cropped in the ordinary course, and which would therefore be in a much higher "condition" than the soil of the drain-gauges, as much, or even more nitrogen as nitric acid, has been found to be present in the autumn, to the depth of 18 or 27 inches.

As the three drain-gauges of unmanured and uncropped soil have been in operation since September 1870—that is, for 30 Harvest-years to the end of August 1900—it is obviously of interest to consider whether or not there is evidence of decline in the amount of nitric acid annually formed in the soil over that period. As the drainage waters were not systematically sampled and analysed until 1877, accurate estimates of the amount of nitric acid in the drainage of the first 7 years of the experiments cannot be made; but the indication is, that it averaged more over those earlier than over the subsequent years. Examination of the results for the four 5-yearly periods of the 20 years, 1877-8 to 1896-7, shows that the average annual loss of nitrogen per acre in the drainage was, over the first 5 years considerably more than the average of the 20 years, but over the second 5 it was less than the average, and over the third 5 less than over the second; whilst over the last five years (1892-3 to 1896-7) the loss somewhat exceeded that of the preceding five years. The details show, that the excess over the first 5 years was due to very excessive amounts in the second and fourth years of the twenty; and that these were coincident with very excessive amounts of rain and of drainage. The loss over the second 5 years was considerably less than over the first, and somewhat lower than the average, and so also was the amount of rain, though the drainage was, on the average, slightly higher. The loss over the third 5 years was less than over the second, and less than the average, and so also were the average amounts of rain and drainage. Over the last 5 years again, the distinctly lower than average loss of nitrogen in the drainage, was coincident with lower than average rainfall, and generally lower than average drainage, especially in the first and fourth years.

With this general decline in the loss of nitrogen in the later years, there was, on the other hand, in the 8th year of the 20 considerably more than the average loss, in the 9th about the average, and in the 11th, 17th and 20th years considerably more, and in the 18th year rather more than the average; part of the excess in the 17th year (1893-4) being probably due to accumulation during the preceding year of drought. In each of the last four years of the first 15, however, the loss was considerably below the average, and in the 16th year, a year of drought (1892-3), there was, with nearly the lowest rainfall and drainage, also nearly the lowest loss of nitrogen by drainage. Lastly as to the details:—in October of the fifteenth Harvest-year (1891-2), there was, with a great excess of rain and drainage, very much more than the average amount of nitric acid in the drainage of that month. Indeed, in only one month during the preceding 14 years, namely in September 1880, was there more nitric acid passing through the 20-inch gauge than in October 1891. There was, however, in October of the 17th year, 1893-4, and in November of the 19th year, 1895-6, about as much loss of nitrogen as nitric acid as in October 1891. More pertinent still is the fact, that in September of the Harvest-year, 1896-7, which is the 27th of the parallel rain and drainage records, and the 20th of the monthly analysis of the drainage waters, there was, with the heaviest rainfall and drainage ever recorded at Rothamsted for a single month, also the greatest loss of nitrogen as nitric acid by the drainage, in any one month of the 20 years, and this was the case with the 20-, the 40-, and the 60-inch drain-gauges.

Obviously, the loss of nitrogen as nitric acid through the soil-drain-gauges was very directly dependent on the amount, and on the distribution, of the rain, and of the drainage. Indeed, although there seems to be some indication of a decline in the amount of nitric acid formed over the later than over the earlier years, the evidence is certainly not yet very conclusive. Thus, examination of the figures shows, that the loss of nitrogen was considerably higher in the 20th Harvest-year, 1896-7, than the average of the 20 years. On the other hand, it was actually lower in the 21st year, 1897-8, than in any of the preceding 20 years. In 1898-9 it was rather under, and in 1899-1900 over average. During the 9 months of the current Harvest-year, ending with May 1901, it was about average.

Finally, according to a revised estimate for the 30 Harvest-years ending with August 31, 1900, there has been a loss of nitrogen through the 20-inch gauge of nearly 17, through the 40-inch of 9, and through the 60-inch of more than 7½ per cent., of the total combined nitrogen in the soil and subsoil.

C

NUMERICAL SUMMARY OF RESULTS RELATING TO RAINFALL AND DRAINAGE AT ROTHAMSTED.

In the Tables (pp. 18-19), are given—the average annual Rainfall over the 19 Harvest-years, 1851-2 to 1869-70; that is, from the commencement of the period for which the average produce, of continuous wheat (pp. 30-1), and of continuous barley (pp. 26-7), is given, up to the time when the experiments with the drain-gauges commenced. Next are given the averages of both rainfall and drainage for the first 7 Harvest-years during which drainage as well as rainfall was collected (1870-1 to 1876-7). Up to that time, the nitric acid in the drainage water had only been occasionally determined; but from 1877-8, up to the present time, it has been determined in proportionally mixed samples for each month; and the Table shows, in inches, the rainfall, and the drainage through each of the three soil-drain-gauges, respectively of 20, 40, and 60 inches depth of soil; also the difference (rainfall collected in the large gauge, $\frac{1}{1000}$ acre area, minus drainage), approximately representing evaporation. The Table further shows—the amounts of loss of nitrogen, in lb. per acre, in the drainage through each of the three drain-gauges, reckoned both as nitrogen, and as nitrate of soda (commercial, 5 per cent. impurity), for each of the 23 Harvest-years 1877-8 to 1899-1900; the maximum and the minimum annual rainfall, with the corresponding drainage, evaporation, and loss of nitrogen, over the 23 Harvest-years; and the averages for each of the four successive five-yearly periods, to 1896-7 inclusive; also the results for the 21st, 22nd, and 23rd, Harvest-years, 1897-8, 1898-9, and 1899-1900. Then are given, averages for four-monthly periods, and for the total Harvest-year, over the 20 years, 1877-8 to 1896-7. There are also given, in the last four divisions of the Table (p. 19)—first the average loss for each month, over the 20 years; secondly, the monthly results for the Harvest-year, 1898-9; thirdly, those for the last complete Harvest-year, 1899-1900; and lastly, similar results for the current Harvest-year (1900-1901) up to May inclusive.

PLAN OF THE PLOTS IN THE PARK, ON WHICH EXPERIMENTS HAVE BEEN MADE,
ON THE MIXED HERBAGE OF PERMANENT GRASS LAND.

46 years, 1856-1901 inclusive.

[For a brief summary of results and conclusions, see opposite page.]

Total area under Experiment about 7 acres.

Area of Plots. { 1, 2, 3, 4-1, 4-2, 11-1, 11-2, and 12, each $\frac{1}{4}$ acre.
5, 6, 7, 8, 9, 10, 13, and 18, each $\frac{1}{2}$ acre.
14, 15, 16, and 17, each $\frac{1}{4}$ acre.
19 and 20, each $\frac{1}{2}$ acre.

[For details of the manuring and produce, see pp. 22 and 23.]

RESULTS OF EXPERIMENTS MADE IN THE PARK, ON THE MIXED HERBAGE OF PERMANENT GRASS-LAND.

These experiments were commenced in 1856, so that 1901 is the 46th year of their continuance.

In the experiments with individual crops grown separately, on arable land, it was found, that those of the same natural Order—Wheat, Barley, and Oats, for example—had certain characters and manurial requirements in common; that those of the Leguminous Order had widely different characters and requirements; whilst crops of other Orders, such as Root-crops, Potatoes, &c., exhibited characteristics differing from the Gramineous, and more from the Leguminous crops. Compared with the conditions of growth of such individual crops grown separately, those of the *Mixed Herbage of Grass-land* are extremely complicated. It comprises, besides numerous Gramineous and Leguminous species, representatives of many other Natural Orders; and of some of great prominence and importance as regards their prevalence and distribution in vegetation generally. If, under the influence of characteristically different manures, there are notable differences in the degree of luxuriance, and in the character of development of closely allied plants when each is grown separately, and much greater differences between plants of different Orders when so separately grown, it is only what might be expected, that there should be very remarkable variations of result when different manures are applied to an already established Mixed Herbage of perhaps some 50 species growing together, representing perhaps nearly 20 Natural Orders.

Accordingly, even in the early years of the experiments, it was observed that those manures which were the most effective with Wheat, Barley, or Oats—that is with Gramineous species grown separately—were also the most effective in bringing forward the *grasses proper*, in the Mixed Herbage. Again, those manures which were the most beneficial to beans or clover, the most developed the Leguminous species in the Mixed Herbage, and *vice versa*. There was also great variation in the predominance of individual species among both the grasses, and the representatives of other Orders. And again, there was very great difference in the tendency to produce merely increased leafy vegetation on the one hand, or to develop stem and seed formation on the other, according to the manure employed. Thus, the final product—the *hay*—was one thing when grown under certain manurial conditions, and quite another when grown under others. For example, the unmanured produce on the average included nearly 50 species—about 17 grasses, 4 leguminous plants, and 27 or more of other Orders; whilst the hay contained from 65 to 70 per cent. of gramineous produce, about $7\frac{1}{2}$ of leguminous herbage, and 20 to 25 per cent. of herbage of other Orders. Compared with this, the produce by farmyard manure contained fewer species, a higher proportion by weight of gramineous, and lower of both leguminous and miscellaneous herbage. Or, to take an extreme case, an excessive application of both mineral and nitrogenous manures for many years in succession, has reduced the number of species traceable, to only about 15, whilst gramineous herbage has contributed from 95 to 98 per cent., or even more of the total hay, leguminous herbage has been excluded, and miscellaneous herbage nearly so. It may be said that any manure that increases the luxuriance of some individual plants, more or less reduces the number of species, and of course alters the proportion of the different species in the final product—the hay; whilst there will, according to the conditions, be different proportions of leaf and stem, and different tendencies to maturation. It is obviously, therefore, very difficult to summarise in a few sentences the results of experiments with 20 different conditions of manuring, carried on over a period of more than 40 years.

It may be said, that the effect of purely nitrogenous manures, such as nitrate of soda, and more still, ammonium-salts, is to reduce the total number of species, characteristically to increase the growth of gramineous species, almost to exclude leguminous herbage, and to reduce the number and proportion of miscellaneous species, but to increase the luxuriance of a few of those that remain. Purely mineral manures, supplying abundance of potash and phosphoric acid, in a less degree reduce the total number of species, do not increase the luxuriance, though they favour the stemminess and maturation of the grasses, but reduce the percentage by weight of such herbage in the hay. Such manures, however, greatly increase the luxuriance, and proportion by weight in the hay, of leguminous species; whilst they reduce, both the number of species, and proportion by weight in the hay, of the miscellaneous herbage.

It is thus obvious that the weights of hay per acre yielded under the varying conditions of manuring, do not represent the comparative value of the produce grown under the different conditions. For example, there has been an average of only about 1 ton per acre of first-crop hay without manure, the produce being, however, the most complex of all. With purely mineral manures, containing potash, the average annual yield of first-crop hay has been rather more than $1\frac{1}{2}$ ton; with fewer species, but containing a considerable proportion of leguminous herbage; in fact, the hay grown by such manures, is of better quality than that produced by any other of the manures in the series. With an excess of mineral and nitrogenous manures together, the average yield per acre has been nearly 3 tons of first-crop hay; but the produce has contained no leguminous, and very little miscellaneous herbage, and from 95 to 98 per cent. of gramineous herbage, perhaps 90 per cent., consisting of only 4 to 6 of the most freely growing and coarser species, which have been characterised by great stemminess. Further, it may be stated, that the one ton of the very complex unmanured hay would contain about $7\frac{1}{2}$ lb. of phosphoric acid, about 25 lb. of potash, and about 30 lb. of nitrogen; that the $1\frac{1}{2}$ ton of hay grown by the purely mineral manures, with its ripened grasses, and large proportion of leguminous herbage, would contain about 18 lb. phosphoric acid, 75 lb. of potash, and 50 lb. of nitrogen; whilst the 3 tons of almost exclusively gramineous, and very stemmy hay, grown by excessive amounts of mineral and nitrogenous manures together, would remove about 30 lb. of phosphoric acid, about 145 lb. of potash, and about 108 lb. of nitrogen.

Between the extremes above indicated, the 20 plots afford examples of very great variety, not only in quantity of produce, but also in quality, depending on both the botanical and chemical composition, and on the character of development of the plants. The experiments were not arranged to provide exact examples for practice, but to ascertain the characteristic effects of different manurial agents on the quantity and quality of the Mixed Herbage, and thus to afford data for application in actual practice. The general result has been to show, that if artificial manures are largely or mainly relied upon, certain descriptions of herbage will be unduly forced at the expense of others, and also that the character of development of the plants will be materially affected. In order to maintain a due admixture of herbage on grass-land mown for hay, farmyard or stable dung should be liberally applied; and it is also conducive to the same end to consume the second crop on the land, with cake or corn. The more a good condition of the herbage is induced and maintained by such means, the more safely may some increased luxuriance, and so increased produce, be obtained, by the judicious use of artificial manures. Provided dung be liberally used, it will not as a rule be necessary to apply potash artificially; but phosphate may advantageously be used as basic slag, and nitrogenous manure in the form of nitrate of soda, which, however, should seldom be used at the rate of more than 1 cwt. per acre.

For details of the manuring and produce of the different plots, see pages 22–23.

The Land has probably been laid down with Grass for some centuries. No fresh seed has been artificially sown for more than 60 years certainly; nor is there record of any having been sown since the Grass was first laid down. The experiments commenced in 1856, at which time the character of the herbage appeared fairly uniform over all the plots. The present season, 1901, is therefore the 46th year of the experiments. Excepting as explained in the Table, and in the foot-notes, the same description of Manure has been applied year after year to the same plot.

During the first 19 years of the experiments, 1856-1874, the first crops only, each year, were mown, made into hay, removed from the land, and weighed. As a rule, the second crops were fed-off by sheep having no other food, the object being not to disturb the condition of the manuring. A given number was allotted to each plot, according to the amount of produce, penned upon a portion of it, and the area extended, day by day, until the whole was eaten down. Frequently, however, the animals suffered considerably; and in 1866, 1870, 1873, and 1874, the second crops (and third, if any) were cut, and spread on the respective plots. In the twentieth season, 1875, the second crops being unusually heavy, and the weather favourable, they were, for the first time, cut, weighed as hay, and removed. In 1876 they were cut and spread on the plots. In 1877 and 1878 the second crops were made into hay, weighed, and removed. In 1879, 1882, 1891, 1892, 1894, 1896, 1897, 1898 and 1900, the second crops were cut, sampled, carted, and weighed, green; the dry matter in the weighed samples was determined, and the produce reckoned into hay by adding one-fourth to the calculated dry matter per acre. In 1880, 1881, 1883, 1886, 1888, 1889, 1890, 1893, and 1895, the second crops were again made into hay, weighed and removed; and it is intended in future to adopt this plan whenever the weather will permit. In 1884, 1885, and 1887, owing to the dryness of the seasons after cutting the first crops, there was but little growth; the second crops were therefore again cut, but spread on the respective plots; and in 1899, Plots 9, 10, 11-1, 11-2, 13, and 14, were also so treated. Owing to the change in the treatment of the crops, the average produce per annum is given, separately, for the first 20 years, 1856-1875, first crops only; and for the succeeding 24 years, 1876-1899, first and second crops (¹²).

(Area under experiment,

PLOTS.		1 acre = (about) 0.404 Hectare or 1.585 Prussian Morgen.		1 lb. (pound avoird.) = (about) 0.453 Kilogramme or 0.907 Zollverein Pfund.		1 cwt. (hundredweight) = (about) 50.8 Kilogrammes or 1.016 Centner.		1 ton = (about) 1015.6 Kilogrammes or 20.32 Centner.	
		1 lb. per acre = (about) 1.12 Kilogramme per Hectare or 0.572 Zolv. Pfd. per Pr. Morgen.							
		1 cwt. per acre = (about) 125.6 Kilogrammes per Hectare or 0.641 Centner per Pr. Morgen.							
		1 ton per acre = (about) 2512 Kilogrammes per Hectare or 12.82 Centner per Pr. Morgen.							
Manures, per acre, per Annum. [In 1897, and since, 400 lbs. Basic Slag used throughout instead of Superphos.]

17		{ 275 lbs. Nitrate of Soda }							
18		{ Mixture supplying the quantity of Potash, Soda, Lime, Magnesia, Phosphoric acid, Silica, and Nitrogen,							
		{ contained in 1 ton of Hay (commencing 1865) }							
19		{ 275 lbs. Nitrate of Soda, 290 lbs. Sulphate of Potash, and 3½ cwt. Superphosphate (commencing 1872) }							
20		{ 327 lbs. Nitrate of Potash, and 3½ cwt. Superphosphate (commencing 1872) }							

(1) "Ammonium-salts"—equal parts Sulphate and Muriate of Ammonia of Commerce. In 1901, the west half of Plots 9, 10, 11-1, and 11-2, received instead of "Ammonium-salts" as above, Bicarbonate of Ammonia containing an equivalent amount of nitrogen; the west half of Plot 5 also received Bicarbonate of Ammonia equal in nitrogen to 400 lb. of "Ammonium-salts."

(2) "Supersphosphate of Lims," 1856 to 1888 inclusive, made from 200 lbs. Bone-ash, 150 lbs. Sulphuric Acid, Sp. gr. 1.7 (and water); 1889-96, made from high percentage mineral phosphates, and containing 37 p. c., or more, of soluble phos. In 1897, and since, 400 lbs. Basic slag, (C. Blatt & S. & J. had license the Monopole specified 2000 lbs. Superphosphate for the first seven years 1856-1862, but

(3) Plots 6, 8, and 10, had, besides the Manures specified, 2000 lbs. Sawdust per acre per annum for the first seven years, 1856-1862, but without effect. (4) 200 lbs., 1856-63 inclusive. (5) 500 lbs. in 1862 and 1863.

(^a) 800 lbs. 1856-'58; 400 lbs. 1859-'61; 800 lbs. 1862-'81; 600 lbs. 1882 and since.

(7) The application of Silicates did not commence until 1862; 9 years (1862-1870), 200 lbs. Silicate Lime, and 200 lbs. Silicate Soda; 1871, and since 1872, 400 lbs. Silicate Soda. (8) 550 lbs. Nitrate of Soda is reckoned to contain the same amount of Nitrogen as 400 lbs. of "Ammonium-salts."

(*) The Manures specified were first applied in 1859 (previously, 1856-7 and 8, Sawdust only).

PARK.

(23)

PERMANENT GRASS LAND.

On January 7, 1881, coarsely broken chalk, in the condition of moisture in which it was brought from the pit, was applied at the rate of 2000 lbs. per acre, for a length of 49 links down each of the Plots 1 to 13 inclusive; and on February 26, partially dried and finely ground and sifted chalk, was applied to the same portion of the same plots, at the rate of 1000 lbs. per acre. In November 1883, each plot (1 to 20 inclusive) was divided, and upon one-half of each 2000 lbs. per acre of fresh burnt lime (slacked), was applied, in addition to the ordinary manures as stated in the Table; and in November 1887, the other half of most of the plots, also received 2000 lbs. per acre; the exceptions being, that Plot 5 did not receive any in 1887, and that the portions of Plots 11-1 and 11-2, which had received the Lime in 1883, in 1887 received 2000 lbs. per acre more, and the other half which did not receive any in 1883, then (1887) received 4000 lbs. per acre. Lastly, in December 1896, the half of Plot 5, which had not previously received any lime, received 4000 lbs. per acre of freshly burnt lime (slacked); and the other half, which had formerly received 2000 lbs., now received another 2000 lbs. per acre, making in all 4000 lbs., the same as on the other half.

It was not until some years after the application of chalk, early in 1881, to small portions of some of the plots as above referred to, that the effects were sufficiently marked to render it desirable to cut and weigh the produce separately; and it was not until 1884 that it was so treated. The produce of the whole of these chalked portions was, however, excluded from the reckoning of the average produce of the plots, as given in this annual report, in the case of all the first crops of 1881, 1882, 1883, and 1886 to 1900 inclusive. It was also excluded in 1884 and 1885, in the case of the plots where the produce was separately weighed (Plots 6, 7, and 8, 1884, and 3, 6, 7, 8, and 11-1, in 1885), but included in the other cases in those two years. Again, in the case of the second crops, it was only in those of 1881 (a few of those of 1882), 1886, 1891, 1892, 1894 and 1896 (excepting Plots 6, 7, and 8), 1897, 1898, and 1900, that the produce of the chalked portions was included. In the case of the remaining or main portion of the plots, to one-half of which a dressing of slacked lime was applied in November 1883, and to the other half in November 1887, there has, on some plots, been marked effect, but it is the average produce of the two portions that has each year been given, as the produce of the plots. Below is given, besides the usual averages, the produce for both 1899 and 1900.

For Plan of the Plots, and brief summary of results and conclusions, see pp. 20-21.

⁽¹⁰⁾ Averages of 8 years, 10 years, and 18 years, as these experiments did not commence until 1868.

⁽¹¹⁾ Averages of (1 year), 10 years, and 11 years, as the experiment only commenced in 1865.

⁽¹²⁾ In 1888 and 1899, the first crops being got up in bad condition, the weights of hay per acre were corrected by adding one-fifth to the determined dry substance. This corresponds to an uniform amount of 16 $\frac{1}{2}$ per cent. of moisture in the first crops of hay.

⁽¹³⁾ As in 1876 the second crops were not removed, those of 1875, which were, are brought in instead; and as also in 1884, in 1885, in 1887, and in 1899, the second crops were not removed, the aggregate second crops of the 20 years (1875, 1877-83, 1886, and 1888-98) are divided by 24 in estimating the average amount of produce of second crops removed per annum over the 24 years. See also Note ⁽¹⁷⁾.

⁽¹⁴⁾ Averages of 22 years only, 1876-97.

⁽¹⁵⁾ In 1899, the second crops were too small to weigh or remove.

⁽¹⁶⁾ In 1900, as in '79, '82, '88, '90, '91, '92, '94, '96, '97, and '98, the second crops being got up in bad condition, the produce of hay per acre was corrected by adding one-fourth to the determined amount of dry substance. This corresponds to an uniform amount of 20 per cent. of moisture in the second crops of hay.

for 50 years in succession, 1852 to 1901 inclusive.

[For a brief summary of results and conclusions, see opposite page.]

Total area of ploughed land about $5\frac{1}{2}$ acres.

Area of Plots. { 1, 2, 3, and 4, of Series O, Series A, and Series C, each $\frac{1}{11}$ acre.
 { 1, 2, 3, and 4, of Series AA, and Series AAS, each $\frac{1}{11}$ acre.
 { 1 N, 2 N, 5 O, and 5 A, each $\frac{1}{11}$ acre.
 { 6-1 and 6-2, each about $\frac{1}{2}$ acre (0.137 acre).
 { 7-1 and 7-2, each about $\frac{1}{2}$ acre (0.118 acre).

The double lines indicate division paths between plot and plot.

[For details of the manuring and produce, see pp. 26 and 27.]

RESULTS OF EXPERIMENTS MADE IN HOOS FIELD ON THE GROWTH OF BARLEY,

for 50 years in succession on the same land—without manure, with Farmyard manure, and with various artificial manures.

The results show, that on the growth of Barley year after year on ordinary arable land, the produce by mineral manures alone is higher than that without manure; that nitrogenous manures alone give more produce than mineral manures alone; and that mixtures of both mineral and nitrogenous manures give much more than either used alone—indeed, generally twice, or more than twice, as much as mineral manures alone. Of mineral constituents, whether used alone or in mixture with nitrogenous manures, phosphates were much more effective than mixtures of salts of potash, soda, and magnesia. The averages show that, under all conditions of manuring (excepting with farmyard manure), the produce was less over the later than over the earlier periods of the experiments—a result partly due to the seasons. But the average produce for 48 years of continuous growth of Barley has, in all cases where nitrogenous and mineral manures (containing phosphates) were used together, been much higher than the average produce of the crop grown in ordinary rotation in the United Kingdom; and very much higher than the average in most other countries when so grown.

Barley is appropriately sown in a lighter soil than Wheat; and whilst Wheat is usually sown in the autumn, Barley is as a rule sown in the spring; and hence it relies in a much greater degree on the stores of the *surface* soil. Accordingly, it is more susceptible to exhaustion of the surface-soil in nitrogenous, and especially in mineral supplies; and hence, in the common practice of agriculture, it more generally requires the direct application of mineral manures, especially phosphatic manures, than does Wheat when grown under equal soil conditions. The exhaustion induced by both crops is, however, characteristically that of available nitrogen; and when, under the ordinary conditions of manuring and cropping, artificial manure is still required, nitrogenous manures are as a rule requisite for both crops; and for the spring sown Barley more generally than for Wheat, phosphatic manures also. It is not recommended that Barley should in practice be grown year after year on the same land by artificial manures as in these experiments; but, in addition to the lighter soils on which it is more appropriately grown in ordinary rotation, it may be grown, both in full quantity per acre and of good quality, after Wheat, or other grain crop, on the heavier soils, when the land is clean enough for a second cereal crop.

For details of the manuring and produce of the different plots, see pages 26 and 27.

EXPERIMENTS ON THE GROWTH OF **BARLEY** YEAR AFTER YEAR ON THE

Previous Cropping—1847, Swedish Turnips, with Dung and Superphosphate of Lime, the Roots carted off; 1848, Barley (with clover); 1849, Clover; 1850, Wheat; 1851, Barley manured with Amm.-salts.

First Experimental Barley Crop in 1852. Barley every year since. The crop of the present year, 1901, is, therefore, the 50th Barley crop in succession. Unless stated to the contrary in the Table, or in the foot-notes, the same Manure has been applied year after year to the same Plot. Description of

(Area under experiment,

	1 acre = (about)	0.404 Hectare or 1.585 Prussian Morgen.
	1 bushel = (about)	0.364 Hectolitre or 0.662 Prussian Scheffel.
	1 lb. (pound avoird.) .. = (about)	0.453 Kilogramme or 0.907 Zollverein Pfund.
	1 cwt. (hundredweight) .. = (about)	50.8 Kilogrammes or 1.016 Centner.
	1 bushel per acre .. = (about)	0.9 Hectolitre per Hectare .. or 0.418 Pr. Scheffel per Pr. Morgen.
	1 lb. per acre = (about)	1.12 Kilogramme per Hectare or 0.572 Zollv. Pfd. per Pr. Morgen.
	1 cwt. per acre = (about)	125.6 Kilogrammes per Hectare or 0.641 Centner per Pr. Morgen.

	Manures, per acre, per annum. [In 1898 and since, 400 lbs. Basic Slag used throughout instead of Superphosphate.]
1 O.	Unmanured continuously
2 O.	3½ cwt. Superphosphate of Lime ⁽¹⁾
3 O.	200 lbs. ⁽²⁾ Sulphate Potash, 100 lbs. ⁽³⁾ Sulphate Soda, 100 lbs. Sulphate Magnesia
4 O.	200 lbs. ⁽²⁾ Sulphate Potash, 100 lbs. ⁽³⁾ Sulphate Soda, 100 lbs. Sulphate Magnesia, 3½ cwt. Superphosphate
1 A.	200 lbs. Ammonium-salts ⁽⁴⁾
2 A.	200 lbs. Ammonium-salts, and 3½ cwt. Superphosphate
3 A.	200 lbs. Ammonium-salts, 200 lbs. ⁽²⁾ Sulph. Potash, 100 lbs. ⁽³⁾ Sulph. Soda, 100 lbs. Sulph. Magnesia
4 A.	{ 200 lbs. Ammonium-salts, 200 lbs. ⁽²⁾ Sulph. Potash, 100 lbs. ⁽³⁾ Sulph. Soda, 100 lbs. Sulph. Magnesia, 3½ cwt. Superphosphate }
1 AA.	275 lbs. Nitrate Soda
2 AA.	275 lbs. Nitrate Soda, and 3½ cwt. Superphosphate
3 AA.	275 lbs. Nitrate Soda, 200 lbs. ⁽²⁾ Sulph. Potash, 100 lbs. ⁽³⁾ Sulph. Soda, 100 lbs. Sulph. Magnesia
4 AA.	{ 275 lbs. Nitrate Soda, 200 lbs. ⁽²⁾ Sulph. Potash, 100 lbs. ⁽³⁾ Sulph. Soda, 100 lbs. Sulph. Magnesia, 3½ cwt. Superphosphate }
1 AAS.	275 lbs. Nitrate Soda, 400 lbs. Silicate Soda ⁽⁵⁾
2 AAS.	275 lbs. Nitrate Soda, 400 lbs. Silicate Soda, and 3½ cwt. Superphosphate ⁽¹⁾
3 AAS.	{ 275 lbs. Nitrate Soda, 400 lbs. Silicate Soda, 200 lbs. ⁽²⁾ Sulph. Potash, 100 lbs. ⁽³⁾ Sulph. Soda, 100 lbs. Sulph. Magnesia }
4 AAS.	{ 275 lbs. Nitrate Soda, 400 lbs. Silicate Soda, 200 lbs. ⁽²⁾ Sulph. Potash, 100 lbs. ⁽³⁾ Sulph. Soda, 100 lbs. Sulph. Magnesia, and 3½ cwt. Superphosphate }
1 C.	1000 lbs. Rape-cake
2 C.	1000 lbs. Rape-cake, and 3½ cwt. Superphosphate
3 C.	1000 lbs. Rape-cake, 200 lbs. ⁽²⁾ Sulph. Potash, 100 lbs. ⁽³⁾ Sulph. Soda, 100 lbs. Sulph. Magnesia
4 C.	{ 1000 lbs. Rape-cake, 200 lbs. ⁽²⁾ Sulph. Potash, 100 lbs. ⁽³⁾ Sulph. Soda, 100 lbs. Sulph. Magnesia, 3½ cwt. Superphosphate }
1 N.	275 lbs. Nitrate Soda
2 N.	275 lbs. ⁽⁵⁾ Nitrate Soda
5 O.	200 lbs. ⁽²⁾ Sulphate Potash, 3½ cwt. Superphosphate ⁽¹⁰⁾
5 A.	200 lbs. ⁽²⁾ Sulphate Potash, 3½ cwt. Superphosphate, and 200 lbs. ⁽¹¹⁾ Ammonium-salts
M.	100 lbs. Sulphate Soda, 100 lbs. Sulphate Magnesia, and 3½ cwt. Superphosphate
6 { 1	Unmanured continuously
2	Ashes (burnt soil and turf)
7 { 1	Farmyard Manure 14 tons, 20 yrs., 1852-71; unmanured since
2	Farmyard Manure 14 tons, every year

(1) "Superphosphate of Lime," 1852 to 1887 inclusive, made from 200 lbs. Bone-ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water); 1888-1897, made from high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate. In 1898, and since, 400 lbs. Basic Slag used throughout instead of Superphosphate.

(2) 300 lbs. per annum for the first six years, 1852-7.

(3) 200 lbs. per annum for the first six years, 1852-7.

(4) The "Ammonium-salts" (excepting in 1887), equal parts Sulphate and Muriate of Ammonia of Commerce. In 1887 Sulphate Ammonia only, 225 lbs. per acre, equal in Nitrogen to the "Ammonium-salts" of previous years. In 1901, the south half of Plots 1 A, 2 A, 3 A, and 4 A, received instead of "Ammonium-salts" as above, Bicarbonate of Ammonia containing an amount of nitrogen equivalent to that of the "Ammonium-salts" applied to the other half.

(5) First 6 years, 1852-7, instead of Nitrate of Soda, 400 lbs. Ammonium-salts per annum; next 10 years, 1858-67, 200 lbs. Ammonium-salts per annum; 1868, and since, 275 lbs. Nitrate of Soda per annum. 275 lbs. Nitrate of Soda is reckoned to contain the same amount of Nitrogen as 200 lbs. "Ammonium-salts."

(27)

FIELD.

SAME LAND, WITHOUT MANURE, AND WITH DIFFERENT DESCRIPTIONS OF MANURE.

Barley—29 years, 1852–1880, Chevalier; 10 years, 1881–1890, Archer's Stiff Straw; 7 years, 1891–1897, Carter's Paris Prize; 1898 and since, Archer's Stiff Straw. In the spring of 1894 permanent division paths were laid out between plot and plot. Below is given, besides the usual averages, the produce for both 1899 and 1900.

For Plan of the Plots, and brief summary of results and conclusions, see pp. 24–25.

(6) The application of Silicates did not commence until 1864; in 1864-5-6 and 7, 200 lbs. Silicate of Soda and 200 lbs. Silicate of Lime were applied per acre; but in 1868, and since, 400 lbs. Silicate of Soda, and no Silicate of Lime. These plots ("AAS") comprise, respectively, one half of the original "AA" plots, and, excepting the addition of the Silicates, have been, and are, in other respects, manured in the same way as the "AA" plots.

(7) 2000 lbs. Rape-cake per annum for the first six years, and 1000 lbs. only, each year since.

(8) 300 lbs. Sulphate of Potash, and 3½ cwt. Superphosphate of Lime, without Nitrate of Soda, the first year (1852); Nitrate alone each year since.

(9) 550 lbs. Nitrate of Soda for 1853-4-5-6, and 7; and 275 lbs. only, each year since.

(10) Ammonium-salts also the first year, but not since.

(11) By mistake 400 lbs. in 1880.

(12) Averages of 12, 24, and 36 years, 1864-99.

(13) Averages of 23, 24, and 47 years, 1853-99.

(14) Averages of 17, 17, and 34 years, 1858-78, and 1880-92. The produce of 1879 was not weighed, owing to the foulness of the plot, from the wet season.

(15) Not recorded.

(16) Averages of 20, 28, and 48 years, 1852-99.

(28)

PLAN OF THE PLOTS IN BROADBALK FIELD,
ON WHICH WHEAT HAS BEEN GROWN

for 58 years in succession, 1843-4 to 1900-1901 inclusive.

[For a brief summary of results and conclusions, see opposite page.]

Brick Trench for collecting the Pipe Drainage from each Plot.

Total area of ploughed land about 11 acres.

Area of Plots 3-4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, and 19, each $\frac{1}{2}$ acre

Area of Lands A and B of Plot 2, each $\frac{1}{10}$ acre.

Area of Plot 20, about $\frac{1}{2}$ acre.

The double lines indicate division paths between plot and plot; also a path across the centre of each plot.

[For details of the manuring and produce, see pp. 30-31.]

RESULTS OF EXPERIMENTS IN BROADBALK FIELD ON THE GROWTH OF WHEAT,

for 58 years in succession on the same land—without manure, with Farmyard manure, and with various artificial manures. During the first 8 years, 1844–1851, various mineral and nitrogenous manures were applied, but not as a rule the same from year to year on the same plot. But, from 1851–2 to the present time, the same manures have, with few exceptions, been applied year after year on the same plots.

The results show that, unlike Leguminous crops such as Beans or Clover, Wheat may be successfully grown for many years in succession on ordinary arable land, provided suitable manures be applied, and the land be kept clean. Even without manure, the average produce over 47 years, 1852–1898, was nearly 13 bushels per acre; or more than the average of the whole of the United States of America, including their rich Prairie lands; in fact, about the average yield per acre of the Wheat lands of the whole world. Mineral manures alone give very little increase; nitrogenous manures alone considerably more than mineral manures alone; but the mixture of the two has given very much more than either separately. Indeed, in one case the average produce by mixed mineral and nitrogenous manure was more than that by the annual application of Farmyard manure; and in 7 out of the 10 cases in which such mixtures were used, the average yield per acre was from over 2 to over 8 bushels more than the average yield of the United Kingdom (which is rather more than 28 bushels at 60 lb. per bushel), under ordinary rotation.

It is estimated that the reduction in yield of the unmanured plot over the 40 years, 1852–91, after the growth of the crops without manure during the 8 preceding years, was, provided it had been uniform throughout, equivalent to a decline of one-sixth of a bushel from year to year due to exhaustion; that is irrespectively of fluctuations due to season.

For details of the manuring and produce of the different plots, see pages 30–31.

EXPERIMENTS ON THE GROWTH OF WHEAT YEAR AFTER YEAR ON THE

Previous Cropping—1839, Turnips, with Farmyard Manure; 1840, Barley; 1841, Peas; 1842, Wheat; 1843, Oats; the last four Crops Unmanured.

First Experimental Wheat Crop in 1844. Wheat every year since; and, with some exceptions, nearly the same description of Manure on the same Plots each year—especially during the last 50 years (1852 and since). The Crop of the present year, 1901, is, therefore, the 58th Wheat Crop in succession. From the commencement of the experiments in 1843-4 up to 1876-7 inclusive, the mineral manures, the ammonium-salts, and rape-cake, &c., if any, were sown in the autumn, before the seed; excepting in 1845 and 1853, when, owing to the preceding wet autumn and winter, both seed and manures were spring sown; and for the crops of 1873, 4, 5, 6, and 7, the ammonium-salts applied to Plot 15 were top-dressed in the spring. Nitrate of soda has, however, always been sown in the spring. But, in consequence of the ascertained great loss of the nitrogen of the manures by drainage, especially in wet winters, it was decided to apply only the mineral manures (and Farmyard-manure) in the autumn, and the ammonium-salts, as well as the nitrate, in the spring; excepting on Plot 15, where, for comparison, the ammonium-salts were sown in the autumn. This plan was adopted for the crops of 1878, 1879, 1880, 1881, 1882, and 1883; but for the crop of 1884 and since, each ammonium-plot (except 15) has received 100 lbs. of ammonium-salts in the autumn with the mineral manures, and the balance of their ammonium-salts as a top-dressing in the spring: Plot 15, as already stated, receiving the whole of its ammonium-salts in the autumn.

The description of seed sown was:—for the first 5 years, 1843-4 to 1847-8, "Old Red Lammas"; for the next 4 years, 1848-9 to 1851-2, "Red Cluster"; for the next 29 years, 1852-3 to 1880-1, "Red Rostock"; and for the next 18 years, 1881-2 to 1898-9, "Club" or "Square Head" (Red). For 1899-1900, and since, "Square-Head's Master" (Red).

Notwithstanding very much labour annually bestowed on hand-hoeing, the land had, partly owing to the characters of the seasons, become very foul, *Alopecurus agrestis* (slender fox-tail) being the most prominent and troublesome weed. For the crop of 1889, therefore, down one half the length of the plots (the top), only alternate rows of wheat were sown, in order, as far as possible, to eradicate this and some other plants; the other half (the bottom) being sown in the usual way. For the crop of 1890, on the other hand, the full number of rows was sown on the top half, and only alternate rows on the bottom half of each plot, in order the better to clean that portion. For the crops

(Area under experiment.

PLOTS,		1 acre = (about) 0.404 Hectare or 1.585 Prussian Morgen.
		1 bushel = (about) 0.364 Hectolitre or 0.662 Prussian Scheffel.
		1 lb. (pound avoird.) = (about) 0.453 Kilogramme or 0.907 Zollverein Pfund.
		1 cwt. (hundredweight) = (about) 50.8 Kilogrammes or 1.016 Centner.
		1 bushel per acre .. = (about) 0.9 Hectolitre per Hectare .. or 0.418 Pr. Scheffel per Pr. Morgen.
		1 lb. per acre .. = (about) 1.12 Kilogramme per Hectare or 0.572 Zollv. Pfd. per Pr. Morgen.
		1 cwt. per acre .. = (about) 125.6 Kilogrammes per Hectare or 0.641 Centner per Pr. Morgen.
	Manures, per acre, per annum. [In 1898-9, and since, 400 lbs. Basic Slag used throughout instead of Superphosphate.]	
2 { Land 1	Farmyard Manure 14 tons (commencing '84-5) ⁽¹⁾	
2 { Land 2	Farmyard Manure 14 tons (1843-4 and every year since)

4	Unmanured for Crop of 1852, and since; previously Superphosphate (made with Muriatic Acid), and Sulph. Amm.	
5 (a and b)	200 lbs. ⁽¹⁾ Sulphate Potash, 100 lbs. ⁽²⁾ Sulph. Soda, 100 lbs. Sulphate Magnesia, 3½ cwt. Superphosphate ⁽³⁾	
6 (a and b)	200 lbs. ⁽¹⁾ Sulph. Potash, 100 lbs. ⁽²⁾ Sulph. Soda, 100 lbs. Sulph. Mag., 3½ cwt. Superphos., 200 lbs. Amm.-salts ⁽⁴⁾	
7 (a and b)	200 lbs. ⁽¹⁾ Sulphate Potash, 100 lbs. ⁽²⁾ Sulph. Soda, 100 lbs. Sulph. Mag., 3½ cwt. Superphos., 400 lbs. Amm.-salts	
8 (a and b)	200 lbs. ⁽¹⁾ Sulphate Potash, 100 lbs. ⁽²⁾ Sulph. Soda, 100 lbs. Sulph. Mag., 3½ cwt. Superphos., 600 lbs. Amm.-salts	
9 { a	200 lbs. ⁽¹⁾ Sulph. Potash, 100 lbs. ⁽²⁾ Sulph. Soda, 100 lbs. Sulph. Mag., 3½ cwt. Superphos., 275 lbs. Nitrate Soda ⁽⁵⁾	
9 { b	275 lbs. Nitrate of Soda ⁽⁵⁾ . (For the Crops of 1894 and since, Plot 9b has received the same manures as Plot 9a.)	
10 { a	400 lbs. Ammonium-salts alone, for 1845, and each year since; Mineral Manure in 1844	
10 { b	400 lbs. Ammonium-salts alone, for '45, and each year since (except '46 and '50); Mineral Manure '44, '48, '50	
11 (a and b)	400 lbs. Ammonium-salts, 3½ cwt. Superphosphate	
12 (a and b)	400 lbs. Ammonium salts, 3½ cwt. Superphosphate, and 360½ lbs. ⁽⁶⁾ Sulphate of Soda	
13 (a and b)	400 lbs. Ammonium-salts, 3½ cwt. Superphosphate, and 200 lbs. ⁽⁶⁾ Sulphate of Potash	
14 (a and b)	400 lbs. Ammonium-salts, 3½ cwt. Superphosphate, and 280 lbs. ⁽⁶⁾ Sulphate of Magnesia	
15 a and b)	200 lbs. ⁽¹⁾ Sul. Pot., 100 lbs. ⁽²⁾ Sul. Sod., 100 lbs. Sul. Mag., 3½ cwt. Super. ⁽⁷⁾ ; 400 lbs. Amm. salts, in Autm. ⁽⁸⁾	
16 (a and b)	{ 1852-64, 13 years, 200 lbs. Sulph. Potash, 100 lbs. Sulph. Soda, 100 lbs. Sulph. Mag., 3½ cwt. Superphos., ... and 800 lbs. Ammonium-salts; average produce 39½ bush. Grain, 46½ cwt. Straw 1865-1883, 19 years unmanured; average produce (19 years, 1865-83) 14½ bushels Grain, 12½ cwt. Straw 1884 and since, 200 lbs. Sul. Pot., 100 lbs. Sul. Soda, 100 lbs. Sul. Mag., 3½ cwt. Super., 550 lbs. Nitrate Soda ⁽⁹⁾ 200 lbs. ⁽¹⁾ Sulphate Potash, 100 lbs. ⁽²⁾ Sulphate Soda, 100 lbs. Sulphate Mag., and 3½ cwt. Superphosphate 400 lbs. Ammonium-salts	
(11) { 17 (a and b)	{ 1878-9 to '81-2, 1700 lbs., '83 and since 1889 lbs. Rape-cake, in Autumn. Previously, '52-78, 3½ cwt. Superph. Lime ⁽¹²⁾ , 300 lbs. Sul. Am., and 500 lbs. Rape-cake; av. prod. (27 yrs., '52-78) 29½ bush. Grain, 27½ cwt. straw	
(11) { 18 (a and b)	Unmanured continuously	
(13) 20	Mixed Mineral Manures as Plot 5, and 100 lbs. Mur. Amm. 1852-'83—then discontinued	
21	Mixed Mineral Manures as Plot 5, and 100 lbs. Sulph. Amm. 1852-'83—then discontinued	
22	Mixed Mineral Manures as Plot 5, and 100 lbs. Sulph. Amm. 1852-'83—then discontinued	

(1) 300 lbs. per annum for Crop of 1858, and previously.

(2) 200 lbs. per annum for Crop of 1853, and previously.

(3) "Superphosphate of Lime," up to 1837-8 inclusive, made from 200 lbs. Bone-ash, 150 lbs. Sulphuric acid sp. gr. 1.7 (and water); 1888-9 to 1897-8, made from high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate. In 1898-9, and since, 400 lbs. Basic Slag used throughout instead of Superphosphate.

(4) The "Ammonium-salts" (excepting for the crop of 1887), equal parts Sulphate and Muriate of Ammonia of Commerce. For the season 1886-7 the same quantity of Nitrogen was applied, but mostly as Sulphate Ammonia. In 1901, the second quarter from the top of Plots 6, 7, 8, 10, 11, 12, 13, 14, and 18, received instead of the portion of the "Ammonium-salts" usually applied in the spring, Bicarbonate of Ammonia containing an amount of Nitrogen equivalent to that in the "Ammonium-salts" it substituted.

(5) 9a, 475 lbs. Nitrate Soda in 1852, 275 lbs. in 1853 and 1854, 550 lbs. each year from 1855 to 1884. No Sulphate of Potash, Soda, or Magnesia, or Superphosphate, in 1852, 1853, or 1854. 9b, 475 lbs. Nitrate in 1852, 550 lbs. each year from 1853 to 1884. 550 lbs. Nitrate is reckoned to contain the same amount of Nitrogen as 400 lbs. "Ammonium-salts."

(6) For 1858, and previously—1½ time as much.

(7) For 1872 and previously, made with Muriatic instead of Sulphuric Acid.

(8) 15a, for 1872 and previously, 400 lbs. Sulphate Ammonia, sown in the Autumn; for 1873-4-5-6 and 7, 400 lbs. "Ammonium-salts," sown in the Spring; for 1878 and since, 400 lbs. Ammonium-salts, sown in the Autumn. 15b, for 1872 and previously, 300 lbs. Sulphate Ammonia and 500 lbs. Rape-cake, sown in the Autumn. For 1873 and since, 15a and 15b both alike, as in the text.

(9) Owing to injury to the plant from the full dressing of Nitrate in years of drought, for the crops of 1889 and since, the Nitrate of Soda was top-dressed at twice, one-half being applied each time.

FIELD.

SAME LAND; WITHOUT MANURE, AND WITH DIFFERENT DESCRIPTIONS OF MANURE.

of 1891 and since, however, the full number of rows have again been sown over the whole length of each plot. The amount of produce recorded in 1890 for 1889, was that obtained on the full sown, lower, or worst yielding half of the plots, and was doubtless somewhat too low. That recorded in 1891 for 1890, was that obtained on the full sown, upper, and better yielding half of the plots, which had also been thin sown, and hoed almost up to harvest, in fact, partially fallowed, the year before, and hence, although the season was undoubtedly a high yielding one, there can be no doubt that the produce as recorded was decidedly too high; and, on careful consideration of the results, the mean of the produce of the thick and thin sown portions of the plots has since been adopted for the crop of 1890. Lastly, the produce for 1891, being that of the whole of each of the plots, half of which had been thin sown, that is, partially fallowed in 1890, and the other half in 1889, was again doubtless somewhat too high. Thus, the produce adopted for 1889 was undoubtedly somewhat too low; that for 1890 probably very near the truth; and that for 1891 somewhat too high. The average produce for the three years together is, however, probably very near the truth; and the averages since taken for longer series of years, as given in the *Memoranda* for 1893, and since, are quite immaterially vitiated by the unavoidable irregularities above referred to.

After the crop of the 50th year (1893) was taken off, the two lands "a" and "b" were thrown together, and permanent division paths made between plot and plot. In a few cases in each of the years 1894 to 1898 inclusive, however, the crops on the two halves (a and b) were kept separate at harvest, and the amount of produce grown on each recorded. Below is given, besides the usual averages, the produce for both 1899 and 1900.

A plan of the plots as now arranged is given on p. 28, and a brief summary of the results on p. 29. It should be explained that for many years there were, besides the plots indicated on the plan, the manuring and produce of which are recorded in the Table below, two others, namely, Plots 0 and 1, which were under experiment up to 1883 inclusive, and the manuring and produce of which have been recorded in the *Memoranda* up to 1895, but have since been excluded from the plan and from the annual record. For the manuring and produce of these plots see previous issues of the *Memoranda*; also the Appendix Tables in No. 66 (Series 1) in the list of papers at p. 13.

(16) From 1849 to 1883 one half of this land was unmanured, and the other half received Sulphates of Potash, Soda, and Magnesia; in 1884 the one half was wheat, and the other half fallow.

(17) The Manures of Plots 17 and 18 are, year by year, transposed.

(12) Made with Muriatic instead of Sulphuric Acid.

(13) After the Crop of 1893 had been removed, this plot was joined to Plot 19, and a new Plot 20 was made from land adjoining, which had been unmanured for many years; growing wheat up to 1883 inclusive; and again in 1887 and 1891; Potatoes, 1889; and left fallow 1884, '5, '6, '8, '90, '92 and '93.

(14) Averages of 24, 23, and 47 years, 1852-98.

(15) Averages of 21, 21, and 42 years, 1852-93.

(16) Averages of Mineral Manures, alternated with Ammonium-salts. (17) Averages of Ammonium-salts, alternated with Mineral Manures.

(18) Plot 17 had the Ammonium-salts for the Crop of 1900.

(19) Plot 18 had the Mineral Manures for the Crop of 1900.

(20) Averages of 23, 24, and 47 years only; as, in 1868, owing to a mistake in carting, the produce could not be ascertained. The Plots marked "(a and b)" were, up to 1893 inclusive, duplicate portions, "a" and "b," respectively, and were manured alike; excepting that, for the crops of 1864-5-6 and 7, the "a" portions of Plots 5, 6, 7, 8, 9, 16, and 17 (or 18), received a mixture of soluble Silicates in addition to the other Manures, but, hitherto, without any material effect; and for the crops of 1868 to 1879 inclusive, cut straw (that produced in the previous season) was applied (instead of Silicates) on the "a" portions of Plots 5, 6, 7, 8, 11, 12, 13, 14, and 17 (or 18); also for the crop of 1874, and each succeeding crop to 1879 inclusive, the straw of the previous season was cut up and applied to the "a" portion of Plot 15. For the crop of 1880 and since, the return of the straw has been discontinued.

(21) Averages of 16, 16, and 32 years, 1852-83.

EXPERIMENTS ON WHEAT ALTERNATED WITH FALLOW, AND WHEAT GROWN CONTINUOUSLY.

The results given in the following Table show the produce of Wheat obtained on the Rothamsted soil for many years in succession, after bare fallow, compared with that of wheat grown continuously year after year on the same land, without the intervention of fallow; in both cases without manure.

Hoos-field, in which the experiments on alternate wheat and fallow are conducted, adjoins *Broadbalk-field*, in which wheat has now been grown continuously without manure (also with different descriptions of manure), for 58 years in succession; and the produce of the unmanured plot of that field, is compared with that grown in alternation with fallow, also without manure, in Hoos-field.

The description of seed sown has been the same in the two fields in the corresponding years; namely—for the crop of 1852 "Red Cluster"; for 28 years, 1854 to 1881 inclusive, "Red Rostock"; for 18 years, 1882-1899, "Club" or "Square Head" (Red); and for the crops of 1900, and since, "Square Head's Master" (Red).

During the first or preliminary period of 5 years, 1851-1855, the cropping of the acre set apart for the experiment on wheat alternated with fallow was as follows:—1851, Fallow (after wheat in 1850); 1852, Wheat; 1853, Fallow; 1854, Wheat; 1855, half Fallow, and half Wheat. From that time to the present the respective halves have been alternately fallow and wheat, giving therefore a crop of wheat succeeding fallow, on half the acre each year.

In the upper division of the Table are given the results for each of the five years of the preliminary period; and in the main division are recorded the results for each individual year of the exact experiment, from 1856 up to the present time.

In the first column of each main vertical division of the Table is given the produce *per acre*, on the half acre of wheat after fallow; and in the second column the produce per acre obtained in the adjoining field (Broadbalk), where wheat is grown year after year on the same land. Lastly, in the third column of each of the vertical divisions is given the amount of produce after fallow, + or - that grown year after year on the same land.

The results for the individual years show that during the earlier years of the experiments on alternate wheat and fallow, when the accumulations due to previous treatment were less exhausted, the produce after fallow was more in excess of that grown in the adjoining field year after year on the same land than afterwards. Referring to the two sets of averages at the foot of the Table, it is seen that if (as in the upper of the two divisions), the produce after fallow is reckoned at the yield per acre of the half in crop each year, it gives on the average several bushels more grain, and also more straw, per acre per annum, than where the crop is grown continuously. On the other hand, if the produce after fallow is reckoned (as in the bottom division) at the yield per acre of the whole area, half in crop and half fallow, it gives several bushels less grain, and also less straw, per acre per annum, than where the crop is grown year after year on the same land.

The conclusion to be drawn is, that although there is an increase of produce after fallow compared with that of wheat grown continuously, it is obtained at the sacrifice of a crop every other year; and that a *given area of land* yields more when the crop is grown year after year than when alternated with fallow. The explanation doubtless is, that much of the nitrogen brought into an available condition under the influence of the fallow, is lost by drainage during the long period that the land is without a crop. (Iniment, 1 acre.)

⁽⁵⁾ Owing to the extremely wet condition of the land, especially on the Nitrate plots, it was not sown until April 6, and then with a very unfavourable seed bed; and, there being a heavy fall of snow a week later, the plant came up very irregularly, and much of it perished from standing surface-water.

⁽⁶⁾ Owing to the very wet winter, 1876-7, the land could not be worked in time for sowing, and was therefore left fallow in 1877; no manures being applied.

The experiments were discontinued after 1878.

6	6	6
5	5	5
4	4	4
3	3	3
2	2	Vetch
		Red Clover
		White Clover
		Sainfoin
		Bokhara Clover
		Beans (or Peas)
1	1	Lucerne
		Small Beds see pp. 40-42.
Series III	Series II	Series I

Total area under experiment about 3 acres, divided into 3 Series.

Each Series about 1 acre, divided into 6 differently manured plots.

Series I. Mineral Manures only;

Series II. The Mineral Manures, and Nitrate of Soda;

Series III. The Mineral Manures, and Ammonium-salts or Rape-cake, etc.

There are now 7 different Leguminous plants growing on each plot, namely—Lucerne, Beans (or Peas), Bokhara Clover, Sainfoin, White Clover, Red Clover, and Vetch; as indicated on Plot 2, Series I.

In the spring of 1898, owing to the growing foulness of the plots in recent years, Plot 1 of Series I. (Small Beds), and all the Plots (1-6) of Series II. and Series III., were ploughed up for thorough cleaning; and on Nov. 2 the land was sown with wheat without manure, as a gauge of the effects on the condition of the land, of the growth of the various Leguminous crops. In October 1899, wheat was sown for the second time without manure; and in October 1900, for the third time. (For the results, see pp. 50-52.) For the present, the experiments with various Leguminous crops are, therefore, confined to Plots 2, 3, 4, 5, and 6, of Series I.

[For details of the experiments with Leguminous crops, etc., in Hoos Field, see pp. 39-42, and 44-52.]

RESULTS OF EXPERIMENTS MADE IN HOOS FIELD ON THE GROWTH OF
VARIOUS LEGUMINOUS CROPS,

year after year on the same land, with mineral, and with mineral and nitrogenous manures, commencing in 1848-9. Clover seed was sown 12 times in 29 years, and the plant failed 8 times out of the last 10 trials. The results showed that when Red Clover was thus sown frequently on the same land, there was almost uniform failure. In fact, after the first few years practically no crop was obtained. In 1878, after the cessation of the trials with Red Clover, various other Leguminous plants, of different habits of growth, and especially of different character and range of roots, were sown on the, so to speak, Clover-exhausted land. The result was that whilst Red Clover, which was included in the list of the new experiments, still failed, giving an average of only 22 lbs. of nitrogen per acre per annum in 5 years of crop over 7 years, the more weakly-rooted and more weakly-growing White Clover, which had not been grown on the land for many years, gave an average of 47 lbs. in 6 years of crop over 9 years; the more freely-growing, and deeper-rooting Vetch an average of 75 lbs. over 14 years; Bokhara Clover, 64 lbs. per annum in 11 years of crop over 12 years; and the very deeply, and very powerfully-rooting Lucerne an average of 160 lbs. of nitrogen over 12 years. Here, then, when various other Leguminous plants followed on the Red Clover-exhausted land, some of them grew luxuriantly, and yielded much larger, and in some cases very large, amounts of nitrogen. Further, the surface-soils gained rather than lost nitrogen.

Experiments have also been made with Leguminous crops in Geescroft Field. Thus, Beans were grown year after year on the same land, without manure, with mineral manures, and with mineral and nitrogenous manures—commencing 1847. The results showed considerable increase in the produce, and coincidently in the yield of nitrogen, by the use of mineral manures containing potash, and but little further increase by the addition of nitrogenous manures; notwithstanding that Beans, like other Leguminous crops, contain a much higher percentage of nitrogen, and yield much more nitrogen per acre, than grain crops. Further, on the growth of Beans thus year after year on the same land, the amount of produce, and the yield of nitrogen, declined considerably, both being much less under all conditions of manuring in the later than in the earlier years. The results further showed, however, that, as in the case of the growth of various other Leguminous crops on the Clover-exhausted land (in Hoos Field), so now after the failure of the Beans and decline in the yield of nitrogen in them, on sowing Red Clover with its very different character and range of roots, on the Bean-exhausted land, very large crops of Clover, containing very large amounts of nitrogen, were obtained. Not only was so much nitrogen removed in the Clover crops, but the surface-soil became determinably richer in nitrogen, due to accumulation of nitrogenous crop-residue.

In view of the failure to grow Red Clover continuously on ordinary arable land, it is a fact of much interest that it has been grown for more than forty years in succession on rich garden-soil. There was, however, a much reduced persistence of the plant, a considerably reduced amount of produce, and of nitrogen in it, and with this a considerable reduction of the stock of nitrogen in the soil, in the later than in the earlier years. Nevertheless, the amount of produce over the 40 years, 1854-1893, corresponded to an average yield of nearly 3 tons of Clover hay, containing about 160 lbs. of nitrogen, per acre per annum; quantities which exceed the average produce of the crop grown once in 8 or more years, in rotation on ordinary arable land.

The results, as a whole, indicate a soil source of failure on the arable land, and a soil source of success on the rich garden-soil.

Lastly, experiments at Rothamsted have confirmed those of others in showing that, by adding to a sterilised sandy soil growing Leguminous plants a small quantity of the watery extract of a soil containing the appropriate organisms, a marked development of the so-called leguminous nodules on the roots is induced; and that there is, coincidently, increased growth, and gain of nitrogen.

It is concluded that in the growth of Leguminous crops, such as Clover, Vetches, Peas, Beans, Sainfoin, Lucerne, &c., at any rate some, and sometimes much, of the large amount of nitrogen which they contain, and of the large amount which they frequently leave as nitrogenous residue in the soil for future crops, is due to atmospheric nitrogen brought into combination by the agency of lower organisms. But it is still a question—how far the failure of Clover, or of other Leguminous crops, may be due to the exhaustion of available combined nitrogen, or of mineral constituents, within the range of the roots, and how far to the exhaustion of the organisms necessary for the bringing about of the fixation of free nitrogen.

For further particulars, see pages 7 and 38-53; also Section III. in Nos. 92 and 93, in Series I. of the list of papers at page 14.

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS.

I.—BEANS, PEAS, AND TARES—GEESCROFT FIELD.

EXPERIMENTS on the growth of Leguminous corn-crops (beans, peas, and tares), with different descriptions of manure, were commenced in 1847, about nine acres being devoted to the purpose.

Experiments with BEANS were continued without a break, for thirteen consecutive seasons, to 1859 inclusive; but, during the later years, the crop fell off very much, and the land became very foul.

In 1860 the land was fallowed.

In 1861 a crop of wheat, without manure, was taken.

In 1862 beans were again sown, but with some variation in the manuring.

In 1863 the land was fallowed.

In 1864, 5, 6, 7, 8, and 9, beans were grown, with much the same manures on the same plots, each year, as in 1862.

In the winter of 1869-70, 5000 lbs. of fresh burnt lime were applied per acre, over all the plots.

In 1870 beans were grown with the same manures on the respective plots as in 1864-69.

In October 1870 winter beans were sown (without manure), but the plants were to so great an extent destroyed by the severe weather which followed, that, in April 1871, the crop was ploughed up, and the land left fallow.

During the winter and early spring of 1871-2, the land was so wet that it could not be prepared in time for sowing. It was therefore left fallow for 1872; at the end of May it was subsoiled to a depth of about 12 inches, and re-ploughed in July.

The winter and early spring of 1872-3 were also so extremely wet, that it was again impossible to prepare the land in time for sowing; it was, however, ploughed up towards the end of March, again left fallow, and re-ploughed in July and October (1873).

On February 2, 1874, the land was again set with Beans, but without manure.

In 1875 Beans were re-sown, with the same manures on the respective plots as in 1864-1870; but owing to the wetness of the land in the first instance, and the subsequent hindrance by other spring sowing, they were not put in until April 1 and 2.

The wetness of the winter 1875-6, again prevented the preparation of the land in due time; and, though the manures were sown, and the land ploughed, it was left fallow during the summer of 1876.

Early in October 1876, winter Beans were put in (drilled), without further manuring.

In 1878 the usual manures were sown, and beans were drilled on February 26.

Owing to the wetness of the winter, and the foul condition of the land, it was left fallow in 1879.

Owing to the continued wetness in the autumn, the severe winter, and foulness of the land, it could not be got into order for sowing, and remained fallow in 1880.

During 1880 the land was ploughed, scarified, and partially cleaned, but owing to the wetness of the autumn, and the wetness and severity of the winter, it was again impossible to work it in time for sowing.

In the months of May and June 1881, the land was ploughed, scuffed, and harrowed, and again on July 9-12; since this time, however, the experiments with beans have been finally abandoned.

On February 1-4, 1882, the land was ploughed and cleaned, and on September 6-7 was harrowed, rolled, and sown with grass-seeds. These germinated satisfactorily, but owing probably to the extreme wetness of the succeeding winter months, the plant almost entirely died off.

In April 1883, samples of soil were taken from many of the plots, generally to a depth of 27 inches, but in selected cases to a depth of 72 inches from the surface, and at that time very few grass plants could be seen. After the soil sampling, the whole field was scuffle-harrowed, and sown with Barley and Clover. In order to test the condition of the soil of the different plots of the continuous Bean and the alternate Wheat and Bean land, they were left unmanured; the remaining portion of the field, not recently under exact experiment, receiving 2 cwt. Nitrate Soda, and 2 cwt. Superphosphate per acre.

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

Notwithstanding the repeated failure of the Beans, though on the other hand the land had practically been fallow since 1878, the Clover came up very well, grew very rapidly, and on many of the plots to a great extent smothered the Barley; so that at harvest (1883) there was a very unusual proportion of Clover in the crop. The Clover plant remained strong through the mild winter, and gave heavy crops in June, and in August 1884; the two crops in many cases approaching, and in some exceeding, 4 tons of hay per acre. In 1885, a good plant remained on most of the plots, yielding a cutting on June 23, which in several cases approached, and in one exceeded, 2 tons of hay per acre. In fact, from several of the plots of this bean-exhausted land, the nitrogen in the surface soil of which had been much reduced, and was very low, more than 6 tons of clover-hay per acre, containing more than 300 lbs. of nitrogen, have been taken. It may be added, that the total yield has been greater on some of the previously continuous bean-plots than on those which had grown beans and wheat alternately. (See below.) After the cutting in 1885, the greater part of the land was thrown into the park for permanent grass; only the previously continuous bean-plots being still reserved for future experiment.

The general result of the experiments with BEANS has been that mineral constituents used as manure (more particularly potash), increased the produce very much during the early years; and, to a certain extent, afterwards, whenever the season was favourable for the crop. Ammonium-salts, on the other hand, produced very little effect; notwithstanding that a Leguminous crop contains two, three, or more times as much nitrogen as a Cereal one grown under similar conditions as to soil, &c. Nitrate of soda has, however, produced more marked effects. But when the same description of Leguminous crop is grown too frequently on the same land it seems to be peculiarly subject to disease, which no conditions of manuring that we have hitherto tried seem to obviate.

Experiments with PEAS were soon abandoned, owing to the difficulty of keeping the land free from weeds, and an alternation of BEANS and WHEAT was substituted; the Beans being manured much as in the experiments with the same crop grown continuously as above described. But the wetness of the winter of 1871-72 prevented the sowing of the Beans for the season of 1872; and again the wetness of the autumn and winter of 1872-3 prevented the sowing of the wheat until April 4, 1873, when Nursery wheat was put in, which, however, did not come to maturity, but was cut in the middle of September, yielding about 27 cwt. of gross produce per acre, containing too little corn to be worth thrashing. The land was ploughed in October 1873, and sown with beans February 3, 1874. On October 23, 1874, wheat was sown without manure. Beans should have been sown in 1876; indeed, the manures were sown, but, for the reason stated above, the land was left fallow; and wheat was put in October 24 (1876). In 1878 Beans were drilled, on February 26, with the usual manures. Owing to the wetness of the winter, and the condition of the land, it was left fallow in 1879; and it continued so up to September, 1882 when it was sown with grass-seeds; since which time it has been treated exactly as the continuous Bean Land. (See the bottom of the preceding page, and the top of this.)

In alternating WHEAT with BEANS, the remarkable result was obtained, that nearly as much wheat, and nearly as much nitrogen, were yielded in eight crops of wheat in alternation with the highly nitrogenous beans, as in sixteen crops of wheat grown consecutively without manure in another field, and also nearly as much as were obtained in a third field in eight crops alternated with bare fallow.

Experiments with TARES, like those with Peas, were soon abandoned, and for the same reasons. Beans were at first substituted, with some variation in the description of the manures employed; but this experiment also had to be abandoned.

II.—RED CLOVER (*Trifolium pratense*).1. *Experiments on ordinary arable land.*—HOOS FIELD.

EXPERIMENTS on the growth of Clover, on ordinary arable land, with many different descriptions of manure, were commenced in 1848-9, and, with the occasional interposition of a corn-crop, or fallow, were continued up to 1877, inclusive.

As with other Leguminous crops, the result was, that mineral constituents applied as manure (particularly potash) considerably increased the crops in the early years. Ammonium-salts had little or no beneficial effect, and were sometimes injurious. It may be added, that the beneficial effects of long previous applications of potash have been apparent whenever there was any growth at all. To go a little more into detail:—

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS--*continued*.

In the first year, 1849, the crops were throughout very heavy; especially with mineral, and without nitrogenous manure.

In autumn 1849, wheat was sown, and in spring 1850, Red Clover. In 1851 small cuttings were taken; and in 1852, though the crops were not heavy, there was by no means a failure.

Since that time, however, all attempts to grow clover year after year on this ordinary arable land have failed to give anything like a full crop, or even a plant which would stand the usual time on the ground.

Small cuttings were obtained in the autumns of 1855 and 1859, from seed sown in the spring of those years; and small but rather heavier cuttings in June and August 1865, from seed sown in 1864.

In April 1868, a portion only of the land was sown with Clover, and the plant for the most part died off in the winter.

In April 1869, the same portion was re-sown, and gave a small cutting in September of that year; but the plant again died off in the winter.

In April 1870, Clover was sown over the whole of the experimental land, this time in conjunction with Barley; but on those portions which had also been sown in 1868 and 1869 the plant again died off during the winter and early spring; whilst from those which had not been sown in 1868 and 1869 two small cuttings were taken in 1871.

In the spring of 1872, the plant being then almost entirely gone, the land was ploughed up. It was again ploughed in July 1872, and in March 1873; the intention being to sow some other Leguminous crop; but owing to the wetness and lateness of the season this was not done, the land was again left fallow, and re-ploughed in the beginning of June and the end of July (1873).

On May 4, 1874, the land was again ploughed, and sown with Red Clover seed, May 5, without manure. The plant came up well, and was very forward in September, when the flowering stems were cut down, but left on the land. During the winter and early spring the plant on those portions from which cuttings had been taken in 1871 almost entirely failed, and the land was ploughed up in May, and again in August (1875); whilst on those from which none had been taken since 1869 a fair plant remained, and two small cuttings were obtained, namely on June 23, and on August 9 and 12 (1875). On September 22, this portion of the land was ploughed up.

In May (1876), the whole was re-ploughed, and again in July and September, and left fallow.

In May 1877, Barley and Clover were sown over the whole of the experimental land, without further manuring, but the clover plant completely died off during the winter.

On two occasions (1851 and 1854), heavy dressings of Farmyard dung were applied to some of the plots; and in 1854 some received a dressing of 20 tons of dung, and 5000 lbs. of lime, per acre.

On some portions of the land Clover was sown 12 times during the 30 years, 1848-1877, and more frequently alone than with a corn-crop. In 8 out of the last 10 trials the plant died off in the winter and spring succeeding the sowing of the seed; in 4 of these without giving any crop at all, and in the other 4, only very small cuttings.

In reference to these field experiments on clover, it may be added that, in 1864, a portion of the land was trenched 2 feet deep, and one-third of the manure was mixed with the layer of soil from 24 to 16 inches, one-third from 16 to 8 inches, and the remainder from 8 inches upwards. Owing to the characters of the season, the mechanical condition of the land was at first very unfavourable after this treatment; but, although many years have now elapsed, and the excess of constituents supplied was in some cases considerable, the plant has died off as completely on these plots as elsewhere.

In 1878, the land was devoted to experiments with various Leguminous plants, differently manured. For further particulars see pp. 46-7, and letterpress at pp. 44-5 and 48-52.

In the winter of 1867-8, a number of small beds, each 3 yards $\times$ 2, were arranged on the previously unmanured plot of the experimental land. These were dug, some to the depth of 9 inches, some to the depth of 18, some to the depth of 27, and some to the depth of 36 inches, and sown to the respective depths with different mixtures; supplying in some cases very large amounts of potash, soda, lime, magnesia, phosphoric acid, sulphuric acid, nitrate of soda, &c.

From three similar sized beds, the soil was removed to the depths of 9, 18, and 27 inches respectively, and replaced by soil taken at the same depths from a garden border, on an adjoining portion of which Clover had been grown successfully since 1854 (see pp. 42-4).

In April 1868, clover was sown on the whole of these small beds (as well as on some other portions of the experimental land); but the plant for the most part died off during the following winter.

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

In April 1869, the small beds (and the other portions as in 1868) were re-sown, small quantities of clover were cut in September of that year, but the plant again died off in the winter.

In April 1870, Clover was again sown on the small beds in conjunction with barley (as on all the rest of the experimental land), but the plant again died in the winter.

In the spring of 1871, the small beds were again re-sown, and the three with garden-soil were entirely enclosed, both around and above, by galvanised wire netting. Small cuttings were taken from these small beds in July 1872; and (excepting from the beds of garden-soil, which had yielded considerably more than the others in 1872), larger cuttings were taken in July 1873. The produce was the largest where potash and nitrate of soda were employed, and where they were applied in the largest quantity, and to the greatest depths.

In April 1874, there was still some healthy plant on all the beds, but it was considered to be too irregular to preserve. It was, therefore, dug in. The artificially-manured beds were re-manured as before, but only to the depth of 9 inches, and seed was sown on May 4th, July 6th, and October 22nd; each time the plant coming up well, but subsequently dying off. On the three beds of garden-soil, the plant from the first sowing (May 4), for the most part stood; requiring only to be made good here and there on July 6; and in September small cuttings were taken.

More small beds were arranged in the spring of 1874; on these the manures were dug in, at the various depths, on May 11th to 14th, and the seed sown on May 16th. At this time, the wire netting was removed from above the three beds of garden-soil, but the whole series of small beds was now surrounded with netting, to keep out ground game. One series of the new plots received sulphate of potash only, another nitrate of soda only, and a third the two together. The plants came up fairly well, but there were some blanks in the rows, which were re-sown on October 22 (1874). A cutting was taken on June 22 and 23 (1875) from these new beds; the blanks in the rows were re-sown on July 24; a second cutting was taken on August 17; and the blanks were again re-sown on September 22 (1875). The plant was the most even on the beds with sulphate of potash, less so on those with nitrate of soda, and less still on those with both together. The amount of produce was also greater with each of the manures used separately, than with the mixture of the two.

In May 1875, the plant was entirely gone on the old artificially-manured beds, which were then dug up, and prepared for re-sowing. On the three beds of garden-soil, though the rows were imperfect, some healthy plants still remained, and gave a small cutting on June 22. On July 24 these beds were dug up; and they, as well as the artificially manured ones just referred to, were re-sown with seed. All came up well, but in May (1876), the plants on the beds of garden-soil were entirely gone, and those on the artificially manured ones nearly so, but they yielded small cuttings on July 17 (1876).

The plants on the new artificially manured beds, like those on the older ones, showed failure in the spring of 1876; but also, like them, gave small cuttings in July. All the small beds were dug up in August (1876); the artificially manured ones re-manured as in 1874, the manures dug in to a depth of 9 inches, and seed was sown on September 1, which came up, but the plants died off on all the plots in the winter of 1876-7.

In May 1877, all the small beds were dug up, and sown with Barley and Clover. To try the effects of shelter, the Barley stubble was left unusually high, but the young clover plants completely died off during the winter (1877-8).

In the spring of 1878, the beds were dug up, and cleaned; and they were re-sown with Clover, without further manuring, on June 12 and 13. All came up well, but the plant was almost entirely destroyed by "Fly."

In May 1879, there remained about a quarter of a plant on the plot with the largest amount of mineral manure, including potash, and sown to the greatest depth, and perhaps a third of a plant where the same mineral manures, with nitrate of soda in addition, had been applied; but there was scarcely a single plant on any of the other plots. On June 9 and 10, 1879, all the beds were cleaned, and re-sown with seed, which came up well; but a very wet and cold season following, most of the plants died off during the summer and autumn.

Early in June 1880, all the small beds were cleaned, and forked up; and on June 10, they were re-sown with seed without further manure. All came up well, but the plants were for the most part destroyed by the severe winter which followed. In May 1881, there was perhaps half a plant on two or three only out of the forty small beds; namely, where the mixed mineral manure, including potash, was used without nitrogenous manure; and the greatest vigour was where the manure was applied in the largest quantity, and to the greatest depths. On no other beds, not even on the three made up of garden-soil, was there nearly as much plant; and on May 12 (1881), all the small beds were cleaned, the clover plants forked

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

in, manures also forked in, as in 1876, to a depth of 8 or 9 inches, and clover seed sown, which came up well, but in most cases became very thin during the winter and spring of 1881-82. A small cutting was, however, taken on June 20, and another on August 18, 1882.

In May 1883, the beds were dug up, and sown with *Lucerne* without further manuring, but it gave no crop in that year. On April 3, 1884, the usual Nitrate Plots received Nitrate of Soda at the rate of 1000 lbs. per acre as a top-dressing. From all the plots, three cuttings were taken, viz. on June 27, August 16, and October 7. On March 9, 1885, the Nitrate plots received Nitrate of Soda at the rate of 500 lbs. per acre as a top-dressing; and three cuttings were taken, viz. on June 3, July 22, and October 10. In 1886 three cuttings were taken from all the plots, viz. on June 28, August 11, and December 3; and after the first cutting the usual Nitrate Plots received, on July 13, Nitrate Soda at the rate of 1000 lbs. per acre as a top-dressing. In 1887, three cuttings were taken, viz. on July 2, Aug. 15, and Oct. 12; and in 1888 two cuttings, viz. on July 6 and Sept. 26. In 1889 the usual Nitrate Plots received a solution of Nitrate of Lime, at the rate of 1490 lbs. per acre (= 86 lbs. of Nitrogen per acre); and two cuttings were taken from all the plots, one on July 5, and the other on August 31. In 1890, the plants on the garden-soil plots had almost entirely died off, and these beds were therefore dug up and re-sown with *Lucerne* on May 2; two cuttings were taken from each of the other plots, on July 5 and Sept. 2; and one cutting from the garden-soil plots on Sept. 2. In 1891, two cuttings were taken, viz. on July 8 and Sept. 15; in 1892, two cuttings, on June 27 and Aug. 30. In 1893, three cuttings, viz. on June 23, Aug. 3, and Oct. 5; in 1894, two cuttings, on July 9 and Oct. 28; in 1895, two cuttings, on May 30 and Aug. 2; in 1896, three cuttings, viz. on May 26, July 11, and Sept. 29; and in 1897, one cutting on June 8. After the cutting in June, there was a thin plant on most of the beds. In recent years they have required a great deal of hand-hoeing to keep down the weeds. The growth has usually been the more luxuriant where either Potash or Nitrate of Soda has been applied, but especially where the two were used together.

It will be observed that, although in the earlier years, the three small beds in the field which had been artificially made up of surface-soil and subsoil brought from a highly manured kitchen garden, maintained a plant of clover, and yielded better crops than the artificially manured beds, yet they finally failed quite as much as the rest.

In 1898, owing to the thinness of the plant, and the great prevalence of weeds, the whole of the small beds were ploughed up, and the experiment was abandoned. (See plan and footnote, p. 36.)

2.—*Experiments on rich garden-soil.*

In view of the failures in the attempt to grow Clover continuously on ordinary arable land it is a fact of much interest, that in 1854 Red Clover was sown in a garden, scarcely half-a-mile distant from the experimental field, on soil which had been under ordinary kitchen garden cultivation for probably two or three centuries, and it has shown very luxuriant growth almost every year since.

From the produce of the seed sown in 1854 (March 29), two cuttings were taken in 1854, three in 1855, two in 1856, three in 1857, two in 1858, and two in 1859.

In 1856, the plot was divided into three equal portions, one being left without manure, another receiving gypsum, and the third a mixed mineral manure containing potash. In 1857 the surface-soil was sampled to a depth of 9 inches.

Seed was re-sown in 1860 (end of May); and yielded one cutting in October of that year, two in 1861, two in 1862, two in 1863, and two in 1864.

Seed was again sown in 1865 (April 22); and this sowing yielded one cutting in September of that year, two in 1866, two in 1867, and one very small cutting in April 1868.

Gypsum and the mixed mineral manure were again applied, and seed was re-sown, April 29, 1868; and from this sowing there were obtained two cuttings in 1869, and one in 1870.

The same manures were again applied March 30, and fresh seed was sown April 10, 1871; yielding one cutting in August of that year, two cuttings in 1872, and two in 1873.

Notwithstanding some injury from Dodder in 1873, there still remained too much plant to break up in the spring of 1874; and accordingly fresh seed was sown *between the rows* on May 4, and this failing, again on July 7, 1874. The manures had been applied *between the rows* on April 16. Three very small cuttings were taken in 1874 (in June, July, and September); and a small cutting again in June, 1875.

In 1875 (July 13), the old plants were dug in, and seed again sown, and this failing, seed

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

was re-sown September 22. In spring 1876 there was luxuriant growth, but deficient plant, which yielded two small cuttings, on June 26, and August 7.

In 1876 (September 1), the beds were dug up, and re-sown with seed, which came up fairly, but the plant suffered during the winter, and in May 1877 it was dug up and re-sown. From this sowing a small cutting was taken on September 5, 1877; and three cuttings in 1878 (on June 10, July 26, and November 1).

In May 1879, there remained some fairly vigorous plants, but not nearly enough for a crop, so the ground was dug up (the soil sampled to a depth of 18 inches), the plants then dug in, and fresh seed was sown, on May 21. From this sowing a cutting was taken on September 13.

Owing to injury from Dodder in the autumn (1879), and the subsequent severity of the winter, the plant again died off, and seed was sown afresh on April 17, 1880. From this sowing two cuttings were taken in that year (August 5 and September 24).

In April 1881, there being too much plant to break up, but not enough to cover the ground, the blanks in the rows were re-sown with seed (April 29), and two small cuttings were afterwards taken, on June 23 and August 16.

On April 6, 1882, there being again many blanks in the rows, these were re-sown with seed. Three cuttings were afterwards taken—on June 14, August 8, and October 20, of the same year.

On April 18, 1883, the same manures were sown on the same portions as in 1874, and the ground was dug, the old plants being dug in. Fresh seed was sown on May 17, which gave one cutting on August 13, 1883; three cuttings in 1884, viz. on June 17, August 11, and October 6; and three cuttings in 1885, viz. on June 2, July 16, and August 31.

Owing probably in great part to the severe winter of 1885-6, the plants nearly all died, and on April 14, 1886, the few that remained were dug in, and fresh seed sown, without further manure, from which one cutting was taken on August 11. In 1887, owing to some destruction of the plant by a mole, a portion of the Unmanured Plot was re-sown with seed on April 21. Two cuttings were taken, viz. on July 8 and August 29.

The plant died during the winter, fresh seed was sown on April 13, 1888, the rows were mended on June 12, and a small cutting was taken on September 6. In April 1889, the rows were again mended, after which two cuttings were taken, viz. on June 21 and October 25.

In April 1890, the plants had almost entirely died off; and the beds were therefore dug up and re-sown with seed, which gave one crop, on August 12. Later in the autumn, however, many plants were destroyed by a dog after mice, so that the rows had to be mended with fresh seed, in May 1891, and cuttings were taken on July 15 and September 25.

During the winter of 1891-2 most of the plants died, the ground was therefore dug up and re-sown with seed on May 7, 1892. The seed germinated well, but some of the young plants were destroyed by "Fly," and the rows were mended on May 27, and one cutting was taken on August 26.

During the winter of 1892-3 some of the plants died, and the rows were accordingly mended on April 20, 1893, and cuttings were obtained on June 24, and on August 22.

In 1894 the rows were again mended on April 19 and gave two cuttings on July 9 and September 4. The plants had now become exceedingly thin and the soil covered with seed-weeds; the beds were therefore dug up later in the autumn, left fallow during the winter, and re-sown with seed on April 19, 1895. The seed germinated well, but was afterwards destroyed by "Fly," and was again sown on May 20; but owing to drought and heat the seed did not germinate, and a third sowing was made on July 2; no crop was, however, obtained in 1895.

During the winter of 1895, and early spring of 1896, most of the plants died, the plots were therefore cleaned from weeds, and prepared for re-sowing. On April 23, 1896, the soil was sampled at two places on each of the three portions. Each sample taken was 4 × 4 × 9 inches deep; and a similar sample was taken of the second 9 inches of depth. The top 9 inches of soil of each of the three portions was then taken out, a mixed mineral manure was then dug into the second 9 inches, and a similar quantity of the same mineral manure was mixed with the surface soil, which was then returned to its position. Seed was sown on July 1, which, however, gave no crop.

Most of the plants died during the winter of 1896-7. The beds were accordingly dug up in April 1897, and seed was resown on April 29, and gave two cuttings, viz., Aug. 7, and Oct. 27.

At the beginning of the winter of 1897, there was a strong and even plant; but it gradually declined, and in January, 1898, failure was very marked. On January 27 the plots were microbe-seeded, with the watery extract of the rich kitchen garden soil at Rothamsted. This did not, however, arrest the failure. Many of the plants were covered with a white fungus;

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

the foliage was destroyed, and the crowns blackened and rotted away, very few plants remaining healthy. Early in March specimens of the plants were forwarded to Mr. Carruthers, who decided that they had suffered from the attack of the fungus "*Sclerotinia Trifoliorum*." Eventually, all the diseased plants were taken up, removed, and burnt, and the ashes returned to the soil. The surface soil was also, little by little, removed, very carefully examined, the Sclerotia carefully picked out, and then the soil was returned. About 6 ozs. of the Sclerotia were thus picked out from the surface-soil of an area of not quite 10 square yards. It was thought desirable, however, to apply a fungicide to the soil before resowing with clover-seed, and bisulphide of carbon was selected for the purpose, as leaving less permanent residue than others. Accordingly, a small dressing of this was applied on May 7, and it was immediately raked in. It was hoped that by the application any remaining Sclerotia would be killed, and that the Leguminous nodule-microbes might not be injuriously affected. On June 2, that is nearly 4 weeks after the application of the bisulphide, clover-seed was again sown, and gave two small cuttings, viz., July 19 and Sept. 5.

The plant continued even and strong, and apparently healthy, throughout the autumn and winter; but in April, 1899, indications of failure were observed. On examination on April 26, it was found that about one-third of the plants were dying off. These were carefully dug up and examined, and it was found that most of them had been attacked by the fungus "*Sclerotinia Trifoliorum*"; but some by the "*Tylenchus Devastatrix*," and some by wireworm. On May 9, about twelve more plants were found to have failed, and on being dug up Sclerotia were found on each. By May 18, three more plants had failed, each being affected by the Sclerotia. On June 1, a few more plants were seen to be failing, but the remainder, perhaps nearly one-half of the whole, showed vigorous growth, and gave a cutting on June 30. On July 25 it was found that the Clover plants were still dying off. Accordingly the whole of the plants, both living and dead, were taken up and removed. The underground growth was picked from the soil as far as practicable, burnt, and the ashes returned to the soil. The soil was also carefully looked over for Sclerotia. Several were found, some adhering to the roots, but the most were loose in the soil. Numerous wire-worms, and three large grubs, were found and removed. On March 15, 1900, a dressing of 1 lb. of bisulphide of carbon was applied to the whole area, and was immediately raked into the soil. Seed was sown August 24, but gave no crop. At the present time (June 1901) a fairly healthy but thin plant is growing.

This (1901) is the 48th season of Clover, year after year, on this plot of rich garden ground. From the foregoing statements, it will be seen that seed was sown in 1854, 1860, 1865, 1868, 1871, 1874 (twice—between the rows), 1875 (twice), 1876, 1877, 1879, 1880, 1883, 1886, 1888, 1890, 1892, 1895 (3 times), 1896, 1897, 1898, and 1900; and in addition, the blanks in the rows were filled up in 1881, 1882, 1887, 1888, 1889, 1891, 1892, 1893, and 1894. Including the partial sowings to mend the rows, seed has been sown thirty-four times in the 48 years; only five times in the first 20 years, but 29 times in the last 28. It is obvious, therefore, that the plants stood very much longer in the earlier, than in the later years. It may be added that the produce of the first five sowings (1854, 1860, 1865, 1868, and 1871) was rather more than one and a-half times as much as has been obtained since. Lastly, the reduced persistence of the plant, and the reduced produce, have been coincident with a considerable reduction in the stock of nitrogen in the soil. Still, there has frequently been very luxuriant growth, even in the later years; and the produce over 40 years, to 1893 inclusive, was equivalent to an average of nearly 3 tons of clover hay per acre per annum.

THE EXPERIMENTS WITH VARIOUS LEGUMINOUS PLANTS AFTER RED CLOVER.

The general result of the experiments described at pp. 46-7 has been that very much more nitrogen has been removed in some of the other Leguminous plants than in the Red Clover. The average annual yield in Red Clover over the 5 years of the 8 (1878-85), when there was any crop, was only about 22 lbs. per acre, giving over the 8 years an average of only 14 lbs. of nitrogen. Against this, *Melilotus leucantha* (Bokhara Clover) yielded, in 1879 about 130 lbs., in 1882 about 145 lbs., and over the 8 years (1878-85) an average of about 70 lbs. per acre; *Vicia sativa* (Common Vetch) gave over 3 years (1882-84) an average of 120 lbs., and over the 8 years (1878-85) an average of about 84 lbs.; and, lastly, *Medicago sativa* (Lucerne) yielded, in 1884 nearly 340 lbs., in 1885 about 270 lbs., and over the 6 years (1880-85), an average of about 153 lbs., of nitrogen; and over the 12 years ending 1891, it gave an average of 160 lbs. of nitrogen per acre per annum. Further, as late as 1895 even *Red Clover* yielded very fair produce under some conditions of manuring, and Sainfoin and Bokhara Clover much more; whilst in 1897, and in 1899, Bokhara Clover yielded very large crops.

Notwithstanding these remarkable results, there has, in recent years, been a tendency to failure, especially of the weaker plants; due largely to the difficulty of keeping the land clean.

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

It was, therefore, decided early in 1898 to reduce the area from 3 acres to less than one acre, in the hope that with so much less land it may be possible to keep it properly cultivated and cleaned, and so obviate one serious source of failure—foulness. The five plots of Series I., each with mineral manure only, have yielded the most important results, and they are retained, so that the manure, the crop, and the soil history is substantially continued. (See Plan and footnotes thereto, at p. 36.)

THE PLOTS STILL RETAINED UNDER EXPERIMENT WITH LEGUMINOUS PLANTS.

Plot 2 was previously manured with superphosphate of lime, but under the new arrangement receives basic slag; Plot 3 receives sulphate of potash; Plot 4 sulphate of potash and basic slag (formerly superphosphate); Plot 5 salts of potash, soda, lime, and magnesia; and Plot 6, the same as Plot 5, and basic slag (formerly superphosphate). For details see p. 47.

Each of the five differently manured plots is sown with the seven descriptions of leguminous plant:—namely (1) Lucerne, (2) Beans (or Peas), (3) *Melilotus leucantha* (Bokhara Clover), (4) Sainfoin, (5) White Clover, (6) Red Clover, (7) Vetches.

Lucerne (Nos. 1 and 2).—The seed was sown on a portion of each of the five differently manured plots on June 8 and 9, 1898; and small cuttings were obtained in September. In 1899, fair first crop cuttings were obtained in July, and smaller second crops in August. In 1900 moderate crops were obtained in July. At each of the periods there was more produce by potash and phosphate together (Plot 4), than by either alone. There was also more on Plot 6, with the mixed alkali-salts and phosphate than on Plot 5 with the mixed alkali-salts alone in the first two years, while in 1900 Plot 5 gave rather more than Plot 6. At the present time (June 1901) there is a fairly even and a fairly luxuriant plant on each of the five plots.

Peas or Beans (Nos. 3 and 4).—Beans were sown in April 1898, yielding only small crops; but more on Plot 4 with the potash and phosphate together than with either alone, and again more with the mixed alkali-salts and phosphate than with the mixed alkali-salts alone. In March 1899, Peas were sown, and yielded small crops, but considerably more with the potash and phosphate together than with either separately; and, as in other cases, considerably more with the mixed alkali-salts and phosphate than with the mixed alkali-salts alone. In March 1900, Beans were sown and yielded fair crops. The potash and phosphate together (Plot 4) gave nearly double the produce of either alone, and the mixed alkali-salts and phosphate yielded rather more than the alkali-salts alone. In April 1901, Peas were again sown, and at the present time (June 1901) there is a somewhat thin plant owing to destruction by pigeons.

Melilotus leucantha—*Bokhara Clover* (Nos. 5 and 6).—Seed was sown in June 1898, but no produce was removed. In 1899 there were heavy crops, which were cut in July; and as with other plants there was more produce with the potash and phosphate together than with either separately, and more with the mixed alkali-salts and phosphate than with the mixed alkali-salts alone. After the removal of the crops it was found that most of the plant was dead, and as the land was becoming rather foul it was ploughed up in March 1900, and resown with seed in September, which germinated well, but the plant died during the winter. The land was ploughed up and resown with seed in May, 1901.

Sainfoin (Nos. 7 and 8).—Seed was sown in June 1898, but the growth was not sufficient for any cutting that year. In 1899 the plant was somewhat irregular, and owing to the drought the growth was not luxuriant. Cuttings were obtained in July, yielding, however, much less weights of produce than the lucerne. In July 1900, fair crops were obtained, the phosphate and potash together (Plot 4) yielding more than either alone, and the mixed alkali-salts and phosphate considerably more than the alkali-salts alone. At the present time (June 1901) there is still an irregular plant, though quite enough to preserve.

Trifolium repens—*White or Dutch Clover* (Nos. 9 and 10).—Seed was sown in June 1898, but there was not sufficient growth to yield a cutting in that year; nor was there in 1899, owing to the drought. In July 1900, small cuttings were obtained, the mixed alkali-salts and phosphate (Plot 6) yielding considerably more than any of the other plots. At the present time (June 1901) there is a somewhat irregular plant, but considered enough to leave for a crop.

Trifolium pratense—*Red Clover* (Nos. 11 and 12).—Seed was sown in June 1898, and again in May 1899, but as in the case of the White Clover there was not sufficient growth to yield a cutting in either 1898 or 1899. In July 1900, very small cuttings were obtained either with potash alone, phosphate alone, or with potash and phosphate together; while with mixed alkali-salts alone, and mixed alkali-salts and phosphate together, there were fair crops. During the winter so large a proportion of the plants died, that it was ploughed up. New seed was sown May 1901.

EXPERIMENTS WITH VARIOUS LEGUMINOUS PLANTS.—HOOS FIELD.

The arable land (in Hoos Field) upon which attempts had been made to grow Red Clover in frequent succession since 1849, was devoted to experiments with various Leguminous Plants in 1878; so that the present season, 1901, is the twenty-fourth year of these experiments.

The object was to ascertain whether, among a selection of plants all belonging to the Leguminous family, but of different habits of growth, and especially of different character and range of roots, some could be grown successfully for a longer time, and would yield more produce, containing more nitrogen as well as other constituents, than others; all being supplied with the same descriptions and quantities of manuring substances, applied to the surface soil. Further, whether the success in some cases, and the failure in others, would afford additional evidence as to the source of the nitrogen of the Leguminosae generally, and as to the causes of the failure of Red Clover in particular, when it is grown too frequently on the same land.

Below are given, in a tabular form, lists of the Plants grown in previous years, and now growing (June 1901); and below the Table, the dates of sowing seed are given.

As the details show, there were at first 14 descriptions of Leguminous Plant grown, but that some of these, which more or less failed, have been given up; whilst others have been transferred from one plot to another. Indeed, the object during the last few years has been to reduce the number from 14 to 7, taking two plots instead of one for each description. The land had, however, notwithstanding much hand-hoeing, become very foul, and after cutting the crops of 1892, all but the Medicago sativa plots were ploughed up, thoroughly cleaned, and re-arranged;

(Original area under Experiment, about 3 acres; each plot about 1/8th acre. In 1898, plots 1-6 of Series 3, and Series 2, and plot 1 of Series 1, ploughed up for cleaning and sown with wheat, leaving plots 2-6 of Series 1 under leguminous experiment.)

with one exception (9 and 10), two of the original plots being ploughed into one, and permanent paths of separation left, between the new larger plots; and in 1896, the Medicago sativa on No. 10 having failed, the two lands (9 and 10) were then thrown together, and devoted to Trifolium repens.

As the tabular statement shows, the arrangement at the present time (1901), is as follows:—

- Nos. 1 and 2, Medicago sativa (Lucerne).
- Nos. 3 and 4, Pisum arvense (Field Peas), or Fabia vulgaris arvensis (Field Beans), alternately.
- Nos. 5 and 6, Melilotus leucantha (Bokhara Clover).
- Nos. 7 and 8, Onobrychis sativa (Sainfoin).
- Nos. 9 and 10, Trifolium repens (White or Dutch Clover).
- Nos. 11 and 12, Trifolium pratense (Red Clover).
- Nos. 13 and 14, Vicia sativa (Common Tare or Vetch).

Below, is also given a Table showing the description and quantities of the manures applied to the different plots. Up to 1897 inclusive there were 3 "Series": Series 1, comprising 5 plots, and Series 2 and 3 each 6 plots. The same mineral manure (if any) has been applied to the same plot of each of the 3 Series:—Series 1, mineral manures only; Series 2, the same mineral manures, and nitrate of soda or lime; Series 3, the same mineral manures, with ammonium-salts, or rape-cake, or cows' urine, in addition. The manures have been applied in the quantities per acre stated in the Table, and the foot-notes thereto.

For general result, and further particulars of the experiments, see pp. 44-5, and pp. 48-53.

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—continued.

Vicia sativa, Common Vetch (Nos. 13 and 14).—Seed was sown in April 1898, which yielded small crops in September. Seed was again sown in March 1899, and yielded small crops in July. Seed was also sown in October 1899, yielding small crops in July 1900. Seed was again sown in April 1901, and at the present time (June 1901) there is a thin but fairly even plant.

Still confining attention to the plots retained under experiments with leguminous plants, it may be further explained, that in 1898, before the mineral manures were applied and seed sown, samples of the surface soils were taken where each of the seven different leguminous plants had been grown, on each of the five differently manured plots. The samples were taken primarily for the purpose of obtaining watery extracts for the inoculation of artificial soils, composed of sand and the properly prepared ashes of the plant, in which, in pots in a glass-house, the seven different descriptions of leguminous plant were to be grown; the object being to gain some information as to how far the absence, or the weakly condition, of the microbes involved in the fixation of free nitrogen had probably been one cause of the failure, or of the less favourable growth on the different plots in the field in some cases than in others.

THE POT PLANT EXPERIMENTS IN THE GLASS-HOUSE.

As each of the seven descriptions of leguminous plant had been grown in the field under five different conditions as to manuring, five pots of washed and heated sand, with the ash of the plant, were sown with each description of plant; to be microbe-seeded, respectively, by the watery extract of the surface-soil of the five differently manured plots in the field on which the plant had been grown. There was also, for each description of plant, a pot with similarly prepared sand and ash, but to be microbe-seeded by a watery extract from rich garden soil. Thus, the only supply of nitrogen to the plants was that contained in the seed sown, a very small amount in the sand, and the practically-negligible amounts in the soil extract used for microbe-seeding.

For each description of plant there were, therefore, six pots, respectively microbe-seeded as under:—

Pot 1.—From rich garden soil.

Pot 2.—From Plot 2 in the field, which had been manured with superphosphate only.

Pot 3.—From Plot 3 in the field, which had been manured with sulphate of potash only.

Pot 4.—From Plot 4 in the field, which had been manured with sulphate of potash and superphosphate together.

Pot 5.—From Plot 5 in the field, which had been manured with salts of potash, soda, and magnesia.

Pot 6.—From Plot 6 in the field, which had been manured with both superphosphate, and salts of potash, soda, and magnesia.

The two annuals, beans and vetches, were cut, and the roots taken up, in September 1898.

Beans (No. 2).—Three seeds were sown in each of the six pots on April 16 (1898). The seed of the bean being very large, it would supply much nitrogen to the growing plants. Examination of the roots showed that there had been a considerable development of nodules, which was evidence that the soil-extracts had effectively seeded the growing roots, and was also clear indication that there had been fixation of free nitrogen. It is of interest to observe, too, that in several cases the development of the nodules was greater in the pots microbe-seeded by the extract from the soil of the leguminous plots in the field, than by that from the garden-soil. Nitrogen determinations have not yet been made in the separated nodules; but they have been in the corn, in the stems and leaves, and in the roots; and the results so far show from nearly seven to more than eight times as much nitrogen in the products of growth as in the seed sown. It is remarkable, too, that in the case of this ripened seed-bearing annual, a much larger proportion of the total nitrogen of the products was accumulated in the corn than in the stem and leaves where the microbe-seeding was from a plot in the field where phosphate had been used, than where a salt of potash, or salts of potash, soda, and magnesia without phosphate, had been employed.

Vicia sativa—Common Vetch (No. 7).—The seed was sown on April 19 (1898). The seed of the Vetch is also comparatively large, but very much smaller than that of the Bean, and the three seeds sown in each pot contained only about one-twelfth as much nitrogen as was supplied in the seed in the case of the Beans. Examination of the roots showed that there had been considerable development of nodules on them; but many appeared to be in an exhausted

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

condition, which is what would be expected with a fairly ripened crop. Excluding any nitrogen in the nodules, the amount in the products of growth was in no case so low as twenty, and in most over thirty times, as much as was supplied in the seed sown.

Melilotus leucantha—*Bokhara Clover* (No. 3).—In the first instance six seeds were sown in each of the six pots, on April 27, 1898. The *Melilotus* seed, which is very small, did not germinate well, and some of the pots had to be resown several times. The growth was in fact very irregular, there being one or two plants two or three feet high, and others only as many inches, in the same pot. In pot 2 there was scarcely any growth; and in pot 6 it was very defective. The above-ground growth of all the pots was cut on November 8, 1898, and as there was not sufficient development of shoots from the crown to promise a second growth, the roots were taken up on December 29. There were, however, numerous nodules on the roots of many of the plants, showing that the microbe-infection had been effective, and indicating that there had been fixation of free nitrogen. The nitrogen determinations (excluding any in the nodules) show, in fact, some gain even in the two pots of comparative failure (2 and 6), and in the others there was a variable amount of gain from over 100 to nearly 400 times, as much as was in the seed sown.

The remaining plants, those of longer life, were—White Clover, Red Clover, Sainfoin, and Lucerne.

Trifolium repens—*White Clover* (No. 5).—Six seeds were sown in each pot on May 2, 1898; and later four more were put into pot 3, five more into pot 4, and four more into pot 6, to fill up gaps. Microbe-seeding by soil-extract was first applied on June 15, and the application was repeated at intervals of a few days until the effect was obvious. In this way each of the pots 2, 3, 4, 5, and 6, received five applications, in all equal to about 114 cc. of the soil-extract; but No. 1, with garden soil-extract, required three more applications than the others, equal in total to about 180 cc. of the extract. In fact, the infection seemed to be more successful under the influence of the extract from the field-soil where white clover had grown, than of that from the garden-soil. Towards the end of August the plants in pots 2, 3, 5, and 6, were well in flower, and the produce was cut from pots 2, 5, and 6, on August 22, and from pot 3 on August 30. The first cuttings from pots 1 and 4 were, however, not taken until October 7; but at that time the plants of pot 4 had developed so much growth that the stems fell over the sides of the pot on to the bench, whilst those of pot 1 fell over considerably, but in a less degree. At the same date, October 7, the plants in pots 2, 3, 5, and 6, again showed much growth, but no flowers, and were then cut a second time. Further cuttings were taken from all the pots on May 25, July 3, and August 16, 1899; also on June 8, July 20, September 7, and December 5, 1900; in all eight cuttings from pots Nos. 1 and 4, and nine from Nos. 2, 3, 5, and 6. Excluding any nitrogen in the roots or in the nodules, there are so far, from nearly 2000 to nearly 4500 times as much nitrogen in the products as in the seed sown; indicating, therefore, an enormous gain of nitrogen due to the microbe-seeding. At the present time (June 1901) the plants in each pot are in flower, and will soon be cut again.

Trifolium pratense—*Red Clover* (No. 6).—Six seeds were sown in each pot on May 2, 1898; and later four more in pot 3, and one each in pots 4, 5, and 6, to fill up gaps. In due time after the microbe-seeding, there was fair growth in all the pots, but less than in the case of the white clover. Cuttings were taken from each pot towards the end of August; and again on October 7, 1898; on June 24, and August 15, 1899; also on July 20, September 7, and December 5, 1900—in all, therefore, seven cuttings. There has been less total growth, and less free-flowering, in the case of the red than of the white clover. Red Clover seed is very small, though still much larger than that of the white; and each seed would supply more than 3 times as much combined nitrogen as the white clover seed. The first five cuttings in no case show less than 300, and in some more than 600 times as much nitrogen in the products as was supplied in the seed sown. The nitrogen in the two last cuttings has not yet been determined. At the present time (June 1901), there is fair growth in all the pots, but little tendency to flowering; another cutting will soon be taken, and probably one or more afterwards; and eventually the nitrogen in the roots and in the nodules will have to be brought into account.

Onobrychis sativa—*Sainfoin* (No. 4).—The Sainfoin seed is small, but considerably larger than that of either White Clover, Red Clover, Lucerne, or Bokhara Clover. Three seeds were sown in each of the six pots on April 29; and later two more in pots 1 and 2; three more in pots 3, 4, and 6; and five more in pot 5, to fill up gaps. There were eventually two plants in pots 1 and 6, and three in each of the others. All the pots were microbe-seeded on June 25, July 7, and July 9; but pot 1, with garden soil-extract, had to be seeded three times more, namely, on July 15, 19, and 28; and the other pots were each seeded once more on July 19. The growth in all the pots was more limited than in the case of any of the other plants, but the foliage had the characteristic dark green colour. Cuttings have been taken at seven periods,

F

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

namely, on November 8, 1898; May 24, and August 17, 1899; May 14, July 20, and December 5, 1900; and May 31, 1901. The plants in most of the pots flowered in May 1899, and in May 1900. In July 1899, one dead plant was taken out of pot 1, one out of pot 3, and one out of pot 5; there being then no plant left in pot 3. Nitrogen determinations have been made in each of the first three cuttings, from pots Nos. 1, 2, 4, 5, and 6; and in the two cuttings from pot 3. The results, so far, show some gain of nitrogen compared with that in the seed sown, even in pots 3 and 5, microbe-seeded from the plots in the field which had not been manured with phosphate, and where the growth in the pots was the most restricted; more in pot 1 with garden soil microbe-seeding, and considerably more in pots 2, 4, and 6 microbe-seeded from the plots in the field which had been manured with phosphate;—indeed in these three cases there was from 30 to 40 times as much nitrogen in the products of the three cuttings as in the seed sown. It may be added that the cuttings taken on May 14, 1900, the nitrogen in which has not yet been determined, were in each case more than at either of the preceding cuttings. There was the most from pot 6, less from pots 2 and 4, less from pot 1, and much less still from pot 5.

Medicago sativa—*Lucerne* (No. 1).—The seed of *Lucerne* is very small, about the size of that of Red Clover. Six seeds were sown in each of the six pots on April 25, 1898; and in each of the pots 2, 3, 4, 5, and 6, more were put in from time to time to fill up gaps. The application of soil-extract for microbe-seeding commenced on June 16, and was repeated in the case of all the pots on June 20 and July 9; and the result was satisfactory in the case of each of the five pots where the soil-extract was taken from the *Lucerne* plots in the field. In pot 1, however, treated with extract from rich garden soil, the plants did not recover from the "nitrogen-hunger" stage indicated by pale colour and restricted growth, although the extract was applied five more times up to August 1. On August 10, four of the diminutive pale green plants were therefore removed, and their roots examined, when on a root-fibril of one plant, which had for a few days shown slight increase of colour, some small nodules were found; and two very small nodules were observed on the root-fibrils of the smallest plant, but there were none on either of the other two. The three plants left in the pot were then microbe-seeded by the extract of the surface-soil from the *lucerne* plot 4 in the field, the manure of which had been superphosphate and sulphate of potash. The effect was soon observable, the plants acquiring a bright green colour, and developing activity of growth. The produce has been cut seven times from each pot, namely, on November 1, 1898; on June 24, August 19, and December 9, 1899; and on July 20, September 7, and December 5, 1900. There was comparatively little tendency to flowering in the plants of the first cutting (November 1, 1898), but there was more in pots 2 and 4 than in the rest. In the second cuttings (June 24, 1899), there were some flowering heads in those of pot 2, but not in the others. In the cuttings of August 19, 1899, the only indication of flowering was again in pot 2; and in those of December 9, 1899, there were no flowering heads. In the cuttings of July 1900, the plants in each pot produced flowers, except No. 4. The largest quantity was yielded in that of pot 2. In the cutting of September 7, 1900, the plants in all the pots produced flowers, the most matured were in pots 1 and 5, which yielded some seeding heads. In the cuttings of December 5 none of the plants showed a tendency to flowering. The nitrogen has been determined in each of the first four cuttings. The largest amounts were in the cuttings of June 24, 1899, and next in those of August 19, 1899, whilst the least was in those of December 9, 1899. The largest yield of total nitrogen was in the produce of pot No. 2, next in that of pot 3, then in that of pot 5; pots 4 and 6 coming next, and pot 1, originally seeded with garden soil-extract, giving the least. Calculating the yield of nitrogen determined in the produce in relation to that in the seed sown, it ranged from over 100 to nearly 300 times as much as was supplied in the seed. The produce of the next three cuttings is considerably more than that of the first four, and at the present time (June 1901) there is again a considerable amount of growth in each of the six pots; so that there will be much more nitrogen to credit to the produce in all the pots, besides that in the roots and nodules. It may be stated generally, that there is more tendency to lower and leafy vegetation in the pots microbe-seeded from the plots in the field manured with plenty of potash but without phosphate, and more tendency to the production of stems and flowering when the extract was taken from the soil where phosphate had been applied.

In conclusion, a careful study of the results of these experiments, so far as they have yet been obtained, will show how enormous, under certain conditions, may be the fixation of nitrogen in proportion to the amounts otherwise available to the plants.

THE PLOTS PLOUGHED UP FOR CLEANING, &c.—WHEAT AFTER VARIOUS LEGUMINOUS PLANTS.

As explained in the footnote at the bottom of the plan of the plots on which experiments have been made on Leguminous Plants for so many years (see p. 36), owing to the growing

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

foulness of the land in recent years, it was decided early in 1898 to plough up for thorough cleaning Plot 1 of Series I. (Small Beds), also the whole of the plots of Series II. and Series III. Accordingly, the portions named, comprising more than two acres, and rather more than two-thirds of the original area, were ploughed up in March of that year. The land was ploughed a second time in May, and then scuffled twice and harrowed twice. In July the land was ploughed for the third time. During these various processes a good deal of rubbish was brought to the surface, and with the drought and hot sun most of it was killed, and it was finally ploughed in. The land was re-ploughed early in October, and as it was now considered to be sufficiently clean, wheat was drilled over the whole on November 2; the description being Club Wheat (Red); the land having been harrowed three times before the drill, and once after it.

The land was thus sown with wheat without manure, as a means of gauging the effects of the different treatment of the plots under Leguminous growth. It may be further explained that there had been 3-foot paths separating from one another each of the Plots 1 to 6 of the different Series, and also between each description of leguminous plant, as indicated by the lines shown on Plot 2 of Series I. in the plan. As it was impossible to plough each of the differently manured plots, and each of the different plants separately, Series II. and Series III. were each ploughed, and otherwise mechanically worked, from one end to the other, that is through the six plots and through all the separating paths.

Throughout the period of growth there was a good and even plant of wheat over the whole area, and as the season advanced there was a promise of very heavy crops; showing, however, marked distinctions according to the description of leguminous plant which had previously been grown; the luxuriance being by far the most marked on the lucerne plots, on which the wheat had a very deep green colour, and was early laid quite flat.

As explained in the plan, each of the six plots had been differently manured, and each differently manured plot had had seven different leguminous crops growing upon it. It is obvious that it would have been impracticable to harvest and thresh separately, the produce after each of the seven descriptions of plant, on each of the six differently manured plots, which would have involved the separation, and the threshing and dressing separately, of forty-two different lots. Accordingly, there were mixed together the produce after each description of leguminous plant, each grown under the six conditions as to manuring; thus reducing the number of lots to be dealt with to seven. There is obviously some disadvantage in ignoring the difference of effect of the different manures on the individual leguminous plants; but it was considered to be more important to separate the produce after the different plants, than to take that on each differently manured plot, each of which had grown seven different descriptions of leguminous plant.

As explained in the footnote to the plan, p. 36, wheat was again sown in October 1899, and for a third time in October 1900.

The following Table shows the produce of wheat obtained on the plots of Series II. and Series III., which had been devoted to various leguminous plants from 1878 to 1897 inclusive; with, however, occasional fallow when there was failure of plant, or the land was foul. Results are given for the produce of wheat in 1899, and also in 1900; and columns are left for that of 1901.

WHEAT, 1899, 1900, AND 1901.

Vetches	40	14½		64·4	61·9		5,051	1,360		7,766	2,262	

Referring first to the produce of 1899, owing to the drought and heat of the summer, the crops ripened well, but rather too quickly, and they were cut on August 10 and 11, and carted on August 12. At a glance it is seen that the produce of both grain and straw was very

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

high, as also was the weight per bushel of the grain. Thus, the produce of dressed grain per acre, ranged after the different leguminous crops, from nearly 40 to over 45 bushels; the produce of straw in two cases exceeded $2\frac{1}{2}$ tons, and in the others was not much less: whilst the weight per bushel of the grain was in only two cases under, and in five over, 64 lbs. It has already been stated, that after lucerne, the luxuriance of growth was more marked than after any of the other leguminous plants; but it is seen that the produce of grain was the lowest, and the weight per bushel was also the lowest, owing to the too heavy crop being laid quite early. The growth was also very luxuriant on all the plots, especially after the Sainfoin, the Bokhara Clover, and the Red Clover, and the yield and quality depended much on the condition of the crops when cut.

It may be added, that with the high condition of the land after so many years under leguminous crops, a winter and spring favourable to luxuriance, and great deficiency of rain and considerably over average temperature in the summer, early vegetative activity was followed by favourable ripening and harvest conditions. Under these circumstances, the grains were adjudged by Mr. Hewlins to be upon the whole very well grown, and characterised by great strength; the wheat after Lucerne being the strongest of all, and that after the peas perhaps the weakest. The grains were, in fact, found to contain a high percentage of nitrogen, and there can be little doubt that there was a high condition of the nitrogenous substances.

In the second year the description of wheat sown was "Square Head's Master." There was a good plant on all the plots, though much less growth than in 1899. Nevertheless, the plants again showed more luxuriance after the Lucerne than after any of the other leguminous plants, and the Table shows that the produce of both grain and straw was considerably higher on the Lucerne plots than on any of the others. The produce was, however, on all the plots very much less in 1900 than in 1899. Part of the result would doubtless be due to the great exhaustion of nitrogenous residue in the growth of the large crops of 1899; and part to the season of 1900 being very much less favourable for wheat production than that of 1899. The weight per bushel was also much lower in 1900 than in 1899.

Square Head's Master was again sown for the third crop, that of 1901, and at the present time (June 1901) the wheat shows a good plant on all the plots, though only restricted growth. Still, the Lucerne plots again show more luxuriance than any of the others.

General Conclusions; Fixation of Free Nitrogen, &c.

The general result of the experiments on ordinary arable land in the field has been—that neither organic matter rich in carbon as well as other constituents, nor ammonium-salts, nor nitrate of soda, nor mineral constituents, nor a complex mixture, supplied as manure, availed to restore the clover-yielding capabilities of the land; though, where some of these were applied in large quantity, and at considerable depths, the result was better than when they were used in only moderate quantities, and applied only on the surface.

On the other hand, it is clear that the soil in the garden, which at the commencement contained in its upper layers about four times as much nitrogen as the arable land, and would doubtless be correspondingly rich in other constituents, has supplied the conditions under which clover can be grown year after year on the same land for many years in succession.

The results obtained on the soil in the garden seem to show that what is called "clover-sickness," cannot be due to the injurious influence of excreted matters upon the immediately succeeding crop.

That Clover frequently fails coincidently with injury from parasitic plants, or insects, cannot be disputed; but it may be doubted whether such injury should be reckoned as the cause, or merely the concomitant, and an aggravation, of the failing condition.

The results of the experiments seem, therefore, to exclude the supposition that the *primary* cause of failure is either destruction by parasitic plants or insects, injury from excreted matters, or the shade of a corn-crop, and to indicate that it must be looked for in exhaustion of some kind within the range of the roots.

Still there remain several open questions. Is it exhaustion of certain organic matters rich in carbon, of nitrogenous food, or of mineral constituents? Again: is there an absolute deficiency in the soil of some of the substances in question, or only an unfavourable condition of combination, or, so to speak, of *soil-digestion* of them, for the requirements of Leguminous plants? Or, is there only an unfavourable *distribution* of them within the soil, considered in relation to the extent and character of the *root-range* of the crop? Or, lastly, is the failure connected with the condition, the distribution, or the exhaustion, of the organisms, the development of which in symbiosis with leguminous plants, has been shown to be associated with the fixation of free nitrogen? For further reference to this point, see next page, also page 7.

EXPERIMENTS ON THE GROWTH OF LEGUMINOUS CROPS—*continued*.

In reference to these various questions, it is a fact of much significance that from October 1857 to May 1879, the diminution in the amount of nitrogen in the garden-soil to the depth of 9 inches only, represented approximately two-thirds as much as was estimated to have been taken out in the crops of the 21 intermediate seasons; and it was concluded that there had been reduction in the lower depths also.

The subject cannot be further considered within the limits of this brief notice, which may be concluded by the following quotation from Rothamsted papers ('Journal of the Royal Agricultural Society of England,' vol. xxi. Part I. p. 178; and 'Journal of the Royal Horticultural Society of London,' vol. iii. p. 86, 1872):—

"When land is not what is called 'clover-sick,' the crop of clover may frequently be increased by top-dressings of manure containing potash and superphosphate of lime; but the high price of salts of potash, and the uncertainty of the action of manures upon the crop, render the application of artificial manures for clover a practice of doubtful economy.

"When the land is what is called 'clover-sick,' none of the ordinary manures, whether 'artificial' or natural, can be relied upon to secure a crop.

"So far as our present knowledge goes, the only means of insuring a good crop of Red Clover is to allow some years to elapse before repeating the crop upon the same land."

Experiments at Rothamsted have confirmed those of others, in showing that, by adding to a sterilised sandy-soil growing leguminous plants, a small quantity of the watery extract of a soil containing the appropriate organisms, a marked development of the so-called leguminous nodules on the roots is induced, and that there is, coincidently, increased growth, and gain of nitrogen. There is no evidence that the leguminous plant itself assimilates free nitrogen; the supposition is, that the gain is due to the fixation of nitrogen in the course of development of the lower organisms within the root-nodules, the nitrogenous compounds so produced being taken up and utilized by the higher plant.

It would seem, therefore, that in the growth of leguminous crops, such as clover, vetches, peas, beans, sainfoin, lucerne, &c., at any rate some of the large amount of nitrogen which they contain, and of the large amount which they frequently leave as nitrogenous residue in the soil for future crops, may be due to atmospheric nitrogen brought into combination by the agency of lower organisms. It has yet to be ascertained, however, under what conditions a greater or less proportion of the total nitrogen of the crop will be derived—on the one hand from nitrogen-compounds within the soil, and on the other from such fixation. It might be supposed, that the amount due to fixation would be the less in the richer soils, and the greater in soils that are poor in combined nitrogen, and which are open and porous. On the other hand, recent results obtained at Rothamsted, indicate that, at any rate with some leguminous plants, there may be more nodules produced, and presumably more fixation, with a soil rich in combined nitrogen, than in one poor in that respect.

In conclusion, as referred to above, the question remains—how far the failure of clover, and other leguminous crops, may be due to the exhaustion of available combined nitrogen, or mineral constituents, within the range of the roots, and how far to the exhaustion of the organisms necessary for the bringing about of the fixation of free nitrogen?

For further particulars on the Question of the Fixation of Free Nitrogen, see No. 92, Series I. (in the list of papers at page 14), pages 119–145; or, No. 93, Series I., pages 137–166.

(54)

PLAN OF THE PLOTS IN BARN FIELD,
ON WHICH EXPERIMENTS HAVE BEEN MADE
WITH ROOT-CROPS.

59 years, commencing 1843.

[For a brief summary of results and conclusions, see opposite page.]

Total area of ploughed land about 8 acres.

Area of Plots. { 1, 2, 5, 6, 7, and 8, of each Series, rather over $\frac{1}{4}$ acre (0.14598 acre).
3, of each Series about $\frac{1}{27}$ acre (0.03649 acre).
4, of each Series about $\frac{1}{3}$ acre (0.20074 acre).
9, rather over $\frac{1}{11}$ acre (0.42 acre).

The double lines indicate division paths between plot and plot.

[For particulars of manuring and produce, etc., see pp. 56-85.]

RESULTS OF EXPERIMENTS MADE IN BARN FIELD ON THE GROWTH OF ROOT-CROPS,

for many years in succession on the same land, without manure, with Farmyard-manure, and with various artificial manures—commencing in 1843 ;

Norfolk White Turnips, 6 years, 1843-48 ;

Swedish Turnips, 4 years, 1849-52 ;

(Barley 3 years, 1853-55, without manure, to exhaust as far as possible the residue from previous manuring, and so to equalize the condition of the plots, before re-arrangement of them) ;

Swedish Turnips, 15 years, 1856-70 ;

Sugar-Beet, 5 years, 1871-75 ;

Mangel Wurzel, 26 years, 1876-1901. (In 1898, and since, small areas have been devoted to Sugar-beet—See Plan p. 54 ; also pp. 84-5.)

Root-crops are grown in most Rotations in Europe. Their growth affords an excellent opportunity for cleaning the land ; and they are generally considered to be in a sense restorative crops. But they depend for luxuriant growth on an abundance of nitrogenous as well as mineral constituents within the soil ; and they are generally highly manured. Indeed, when grown in ordinary soil without manure, either for a few years in succession, or even in rotation, they soon revert to the uncultivated condition. The restorative effects of their growth in rotation are in fact due—to the large amount of manure applied for their growth ; to the large residue of the manure left in the soil for future crops ; to the large amount of matter at once returned as manure again in the leaves ; to the large amount of food produced, and the small amount of the most important manurial constituents of the roots which is retained by the animals consuming them—the rest returning as manure again.

Feeding-roots are essentially *Sugar crops*. The *percentage* of sugar is the greater the more mature the roots, and is consequently as a rule the greater in the roots of the smaller crops. But the amount of sugar *produced per acre* is much the greater in the larger crops. The amount of crop, and of Sugar produced, depends greatly on the amount of Nitrogen taken up. The percentage of nitrogen in Feeding-roots is comparatively low, but it is the higher the greater the available supply within the soil, and the more luxuriant and less ripe the crop. A large, but variable, proportion of the nitrogen is non-albuminoid ; the more, the less ripe the crop. The proportion of albuminoid matter to non-nitrogenous food material is very much lower than in ripened products, such as cereal grains for example. The amount of crop, and the percentage and actual amount of nitrogen in the roots, depend very directly on the amount of nitrogen available within the soil ; and it is quite fallacious to suppose that root-crops gain much of their nitrogen from atmospheric sources by means of their extended leaf-surface.

For particulars of the manuring and produce, and to some extent of the composition of the different descriptions of roots grown on the different plots, see pages 56-85.

EXPERIMENTS ON ROOT-CROPS.—BARN FIELD.

Experiments with Turnips were commenced in 1843. Eight acres, divided into numerous Plots, were set apart for the purpose, and the crop was grown for ten consecutive years on the same land; "Norfolk Whites" 1843-1848, and "Swedes" 1849-1852; on some Plots without manure, and on others with different descriptions of manure.

Barley was then grown for three consecutive seasons, 1853-1855, without manure, in order to test the comparative corn-growing condition of the different Plots, and also to equalise their condition, as far as possible, by the exhaustion of some of the most active and immediately available constituents supplied by the previous manuring.

A new series of experiments with Swedes was arranged in 1856, having regard to the character of the manures previously applied on the different Plots, and to the

results previously obtained. This second series was continued for fifteen years, namely from 1856 to 1870 inclusive.

The results obtained in the first three years, 1843, 1844, and 1845, were published in the 'Journal of the Royal Agricultural Society of England,' vol. viii. Part II., 1847. In the upper division of the Table below there is shown the produce obtained Without Manure, and with Farmyard Manure, in the first 3 years, 1843, '44, and '45; and in the subsequent divisions there are given abstracts of the results obtained Without Manure, and with Different Manures, from 1845 to 1870 inclusive.

During the five years, 1871-1875, the land was devoted to experiments with Sugar-Beet, for particulars of which see pp. 58-61.

In 1876 experiments with Mangel-wurzel were substituted, and are still in progress; see pp. 62-83. (In 1898, and since, small areas have been devoted to new experiments with Sugar-beet.—See Plan p. 54; also pp. 84-5.)

(Area under experiment about 8 acres; quantities, average per acre, per annum.)

6	Superphosphate, each year; Sulphate Potash, 1856-1860	2 12	0 9	4 12	0 15
7	Superphosphate, each year; Sulph. Potash, and 36½ Amm.-salts, 1856-60	2 7	0 7	4 5	0 13
8	Unman. 1853, and since; previously part Unman.; part Superphosph.	1 3	0 4	4 12	0 14

NOTE.—"Sulphate of Ammonia" is estimated to contain 23 per cent. Ammonia, and "Muriate of Ammonia" 27 per cent. "Ammonium-salts," in each case, equal parts Sulphate and Muriate of Ammonia of commerce; and the mixture is estimated to contain 25 per cent. Ammonia. The 328 lbs. Nitric Acid (Sp. gr. 1.35), mixed with sawdust, and used as a cross-dressing on the Plots of Series 2, from 1856-1860, were estimated to contain Nitrogen = 50 lbs. Ammonia.

(1) The crops of 1859 and 1860 failed, and were ploughed in; but, as the manures were applied, and there would be accumulation within the soil for the succeeding crops, the average produce is calculated as for 15 years, that is, the produce of the 13 years is, in each case, divided by 15.

EXPERIMENTS ON SUGAR BEET (VILMORIN'S GREEN-TOP WHITE SILESIAN).—BARN FIELD.

GROWN YEAR AFTER YEAR ON THE SAME LAND, WITHOUT MANURE, AND WITH DIFFERENT DESCRIPTIONS OF MANURE, 5 YEARS, 1871-'75.

Previous Cropping:—1843-'48 (6 Seasons), experiments on Norfolk White Turnips, with different descriptions of Manure.

1849-'52 (4 Seasons), experiments on Swedish Turnips, with different descriptions of Manure.

1853-'55 (3 Seasons), Barley without Manure (with a view as far as possible to equalise the condition of the Plots).

1856-'70 (15 Seasons), experiments on Swedish Turnips, with different descriptions of Manure, in which the arrangement of the Plots was the same, and that of the Manures very similar—in fact, exactly the same during the last 10 years—as in the first year of Sugar Beet, excepting that, during those 10

years, the Alkalies were omitted for the Swedes. For the second and subsequent years of Sugar Beet slight alterations in the Mineral Manures were made, and in the fourth and fifth years the Farmyard Manure, Nitrate of Soda, Ammonium-salts, and Rape-cake were omitted, as will be seen below. In 1871, the seed was dibbled on ridges, in rows 26 inches apart, and 10 inches apart in the rows; in 1872-'75, seed dibbled on the flat; in rows 22 inches apart, and 11 inches apart in the rows; plants moulded up afterwards. Roots all carted off, Leaves weighed, spread on the respective Plots, and ploughed in.

Below are given the Manures and Produce for the 5 Seasons, 1871-'75.

Area under experiment, about 8 acres. The experiments are arranged as under, in 5 Series, each of which comprises 8 Plots.

Manures, per Acre, per Annum.

3	Without Manure (1846, and since)	5 9	1 1	9 5	1 12	8 0	1 3	14 1	2 13	11 17	1 10
4	{ 3½ cwt. Superphosphate, 500 lbs. Sulphate Potash, 200 lbs. Chloride } Sodium (common salt), 200 lbs. Sulphate Magnesia	5 9	1 0	9 8	1 7	7 16	1 1	12 14	1 14	10 3	1 7
5	3½ cwt. Superphosphate	5 11	1 2	9 19	1 10	7 16	1 4	13 17	2 8	11 2	1 14
6	3½ cwt. Superphos., 500 lbs. Sulph. Potash	5 4	1 0	8 4	1 4	7 1	1 2	12 8	2 3	10 2	1 9
7	3½ cwt. Superphos., 500 lbs. Sulph. Pot., and Amm.-salts '71, '72, '73	5 11	1 1	8 2	1 6	7 6	1 1	11 17	1 17	10 6	1 11
8	Unmanured, 1853, and since; previously part Unman., part Superphos.	4 15	1 0	7 4	1 2	6 1	1 4	12 2	2 11	11 12	2 13

(1) "Superphosphate of Lime"—in all cases made from 200 lbs. Bone-ash, 150 lbs. Sulphuric Acid, sp. gr. 1.7 (and water).

(2) "Ammonium-salts"—in each case equal parts Sulphate and Murate of Ammonia of Commerce.

(3) Owing to the deficiency of Rain for some time after sowing, a large proportion of the plants failed. Some were transplanted on Plots 1, but not on the other plots; and eventually the plant was (excepting on Plots 1) upon the whole very deficient and irregular, the remaining plants being larger than usual.

EXPERIMENTS ON SUGAR BEET.—BARN FIELD—continued.

SUMMARY OF THE COMPOSITION OF THE SUGAR-BEET ROOTS.

An abstract of the analytical results obtained illustrating the influence of different manures, and different seasons, on the composition of Sugar-beet, is given below. In interpreting the figures it must be borne in mind that with forty different experiments each year, and in each year four, or five, or more times as much produce on some Plots as on others, it would be impossible to sample each at its best, and all in the same condition of ripeness. Each year the seed was sown on all the Plots at the same time; and the samples (each consisting of the vertical fourths of 10 or 15 roots) were taken from all within a period of about a week, beginning with the ripest. It is obvious, however, that the smaller crops would be much riper than the larger ones. The dry matter, ash, and nitrogen, as given in the Table, are determined in the roots themselves; but they have generally been determined in the expressed juice also.

The sugar was determined in the expressed juice, and calculated into its percentage in the roots in accordance with the methods adopted at the time the experiments were made (1871-75), which were founded on the estimate of the percentage of juice in the roots, reckoned from the determined percentage of dry matter in the juice and in the roots. The results showed an average of about 95 per cent. of juice, and this figure was adopted in calculating the amount of sugar in the roots from that determined in the juice. In 1879, however, Scheibler published results obtained by determining the sugar in Sugar-beet, both directly in the roots by extraction with dilute alcohol, and also in the juice in the ordinary way. Whilst the old method indicated an average of about 95 per cent. of juice, the new one showed only about 90 per cent. Scheibler concluded that water equal to the difference (about 5 per cent.) existed in combination with the marc, and this he

termed "colloid water," as distinguished from the water of the juice. In the Rothamsted "Memoranda" for 1881, attention was called to Scheibler's new results and conclusions, and it was pointed out that if they were confirmed the percentages of sugar annually recorded in the Tables of the Rothamsted results should be reduced by about $\frac{1}{10}$ or $\frac{1}{20}$. Subsequently, further evidence, and especially results obtained by Maercker, by the extraction of the sugar in the roots by alcohol, left no doubt that the amount of juice in Sugar-beet averages more nearly 90 than 95 per cent.; and having in 1895 to re-consider the subject for a paper on "Root-crops," the previously annually recorded percentages of sugar in the experimentally grown Sugar-beet, were then corrected on the assumption that the amount of juice will on the average be only 90 per cent., and the results as so corrected are given in the Table below. It is obvious, however, that with roots varying so much in character of growth, size, and ripeness, the percentage of juice would not be the same in all. Nevertheless, it was considered that the results calculated on the assumption of 95 per cent. of juice, approximately and usefully represented the actual and relative amounts of sugar in the various roots; and now that only 90 per cent. of juice is assumed, it may be supposed that the results will be actually nearer the truth than before.

It need only further be observed that although, in comparable cases, the larger crops generally give a juice containing a lower percentage of sugar, and higher percentages of mineral matter and of nitrogen, yet the larger crops yielded very much more sugar per acre.

MANURES, PER ACRE, PER ANNUM, UNLESS OTHERWISE STATED (SEE BELOW).

PLOTS.	ABBREVIATED DESCRIPTION OF STANDARD MANURES. For details, see pp. 58-9.	SERIES 1. Standard Manures only.				SERIES 2. Standard Manures, and Cross-dressed with 550 lbs. Nitrate Soda.				SERIES 3. Standard Manures, and Cross-dressed with 400 lbs. "Ammonium-salts."				SERIES 4. Standard Manures, and Cross-dressed with 2000 lbs. Rape-cake, and 400 lbs. "Ammonium-salts."				SERIES 5. Standard Manures, and Cross-dressed with 2000 lbs. Rape-cake.

(1) Owing to the deficiency of Rain for some time after sowing, a large proportion of the plants failed. Some were transplanted on Plots 1, but not on the other plots, and eventually the plant was (excepting on Plots 1) upon the whole very deficient and irregular, the remaining plants being larger than usual.

EXPERIMENTS ON MANGEL WURZEL. —BARN FIELD (after SUGAR-BEET); commencing 1876.

Below are given the particulars of the Manures and Produce in each of the first 5 Seasons, 1876-1880; also the average Produce of those first 5 Seasons. For continuation, see pp. 66-7, 70-1, 74-5, 78-9, and 82-3.

The arrangement of the Plots is precisely the same as previously for Sugar-beet, inches apart; plants 11 inches apart in the rows (?). Roots all carted off; Leaves excepting that Plot 9, which was unmanured for Sugar-beet, and also previously for weighed, spread on the respective Plots, and ploughed in.

(Area under experiment about 8 acres.)

AVERAGE OF 5 SEASONS, 1876, '77, '78, '79, and 1880.

[illegible]

cases made from 200 lbs. Bone-ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water).

cases made from 200 lbs. bone-ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water).

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD—continued.—SUMMARY OF THE COMPOSITION OF THE MANGEL ROOTS, in each of the first 5 Seasons, 1876-1880; also the average composition over the first 5 Seasons. For the composition in 1881 and succeeding years, see pp. 68-9, 72-3, 76-7, and 80-1.

An abstract of the analytical results obtained, illustrating the influence of different manures, and of different seasons, on the composition of Mangels, is given below. The dry matter, ash, and nitrogen, are of course determined in the roots themselves. The amounts of dry matter, ash, and nitrogen, have also, in many cases, been determined in the expressed juice. In many cases also, the amount of the nitrogen existing as albuminoids has been determined (by Church's method); and in some cases the amount as amides and as nitric acid. It may be observed that by far the larger proportion of both the mineral matter and the nitrogen of the roots is found in the juice; and of the nitrogen in the juice a variable proportion, ranging from less than one-fifth to not more than one-third of the total, is found to exist as albuminoids.

The sugar was determined in the expressed juice, and calculated into its percentage in the roots in accordance with the methods adopted at the time the experiments were made (1876-80), which were founded on the estimate of the percentage of juice in the roots, reckoned from the determined percentage of dry matter in the juice and in the roots. The results showed an average of about 96 per cent. of juice, and this figure was adopted in calculating the amount of sugar in the roots from that determined in the juice. In 1879, however, Scheibler published results obtained by determining the sugar in *Sugar-beet*, both directly in the roots by extraction with dilute alcohol, and also in the juice in the ordinary way. Whilst the old method indicated an average of about 95 per cent. of juice, the new one showed only about 90 per cent. Scheibler concluded that water equal to the difference (about 5 per cent.) existed in combination with the marc, and this he termed "colloid water," as distinguished from the water of the juice. In the Rothamsted "Mémoires" for 1881, attention was called to Scheibler's new results and conclusions, in regard to *Sugar-beet*, and it was pointed out that if they were confirmed the percentages of sugar annually recorded in the Tables of the Rothamsted results should be reduced by about $\frac{1}{10}$ or $\frac{1}{12}$. It was further pointed out, that supposing the same applied to Mangels, and that the amount of true juice in them averaged only

90 instead of 96 per cent. the percentage of sugar in their roots would also be from $\frac{1}{10}$ or $\frac{1}{12}$ less than given in the Table. Subsequently, further evidence, and especially results obtained by Maercker, by the extraction of the sugar in the roots by alcohol, left no doubt that the amount of juice in *Sugar-beet* averages more nearly 90 than 95 per cent. We are not aware of any published results of the determinations of sugar in Mangel-roots by extraction with alcohol; but much direct evidence on the point is available, it is assumed that the amount of juice in Mangels, like that in *Sugar-beet*, will probably average about 90 per cent.; and having in 1895 to reconsider the subject for a paper on "Root-crops," the previously annually recorded percentages of sugar in the experimentally grown Mangel-roots, were then corrected on the assumption that the amount of juice will on the average be only 90 per cent., and the results as so corrected are given in the Table below. It is obvious, however, that with roots varying so much in character of growth, size, and ripeness, the percentage of juice would not be the same in all. Nevertheless, it was considered that the results calculated on the assumption of 96 per cent. of juice, approximately and usefully represented the actual and relative amounts of sugar in the various roots; and now that only 90 per cent. of juice is assumed it may be supposed that the results will be actually nearer the truth than before, and relatively as near.

In interpreting the figures, it must be borne in mind, that, with forty different experiments each year, and in each year four, five, or more times, as much produce on some Plots as on others, it would be impossible to sample each at its best, and all in the same condition of ripeness. Each year the seed was sown on all the Plots at the same time. The sample analysed was in each case a mixture of vertical sections of ten or fifteen roots, and all the samples were as a rule taken within a period of from one to two weeks; as far as practicable beginning with the ripest. It is obvious, however, that the smaller crops would be much riper than the larger ones; but, although the larger crops generally contain a lower percentage of sugar, they yield very much more sugar per acre.

(1) For Plots 1, 2, and 3, the average percentages of Sugar are taken over the last four years only; and in all cases the average percentages of Nitrogen are taken over the last three years only.

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD (after SUGAR-BEET); commencing 1876—continued.

Below are given the particulars of the Manures and Produce of the Sixth, Seventh, Eighth, Ninth, and Tenth Seasons, 1881, 1882, 1883, 1884, and 1885. For the Manures and Produce of the 5 preceding Seasons, see pp. 62-3, and for those of succeeding seasons, see pp. 70-1, 74-5, 78-9, and 82-3.

The arrangement of the Plots, and of the Manures, is precisely the same as for the five preceding years of Mangels, and also the same as previously for Sugar-beet the plots; see note 5, below. Roots all carted off; Leaves weighed, spread on the (see pp. 58-9), excepting that Plot 9, which was unmanured for Sugar-beet, and also respective Plots, and ploughed in.

(Area under experiment, about 8 acres.)

(4) "Superphosphate of Lime"—in all cases made from 200 lbs. Bone ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water).
 (5) Plot 9 sown on the flat instead of on ridges; plants ridged up afterwards; rows 22 inches apart, plants 10 inches apart in the rows.
 (6) Owing to dry weather much seed failed, especially on some Ammonia and Nitrate plots, and the blanks were filled up by transplanting.
 (7) In order to lessen possible loss by drainage, or injury to the seed or young plants, it was decided to top-dress the Nitrate of Soda and Ammonium-salts after the plant was well up, and for greater convenience the seed was sown on the flat; but owing to unfavourable weather, and to the unsatisfactory condition of the land where these manures had been applied without any organic matter for so many years, the plant almost entirely failed, and the Nitrate and Ammonium-salts were therefore not sown at all. On Series 4 and 5, however, where Rape-cake is usually applied, and the soil was more open, the seed germinated, and the plants grew fairly well.
 (8) Owing to the failure of the plant on many plots, and the irregularity of the crops in 1885, the produce of that year is not brought into the average.

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD—*continued*.—SUMMARY OF THE COMPOSITION OF THE MANGEL ROOTS, in the Sixth, Seventh, Eighth, Ninth, and Tenth Seasons. 1881, 1882, 1883, 1884, and 1885. For particulars of the composition in the first 5 Years, 1876–1880, see pp. 64–5, and for those in succeeding seasons see pp. 72–3, 76–7, and 80–1.

An abstract of the analytical results obtained, illustrating the influence of different manures, and of different seasons, on the composition of Mangels, is given below. The dry matter, ash, and nitrogen, are of course determined in the roots themselves. The amounts of dry matter, ash, and nitrogen, have also, in many cases, been determined in the expressed juice. In many cases also, the amount of the nitrogen existing as albuminoids has been determined (by Church's method); and in some cases the amount as amides and as nitric acid. It may be observed that by far the larger proportion of both the mineral matter and the nitrogen of the roots is found in the juice; and of the nitrogen in the juice, is found to exist as albuminoids, ranging from less than one-fifth to not more than one-third of the total, is found to exist as albuminoids. When sugar has been estimated, it has been determined in the letterpress above the Table on p. 64. its percentage in the roots, as described in more detail in the letterpress above the Table on p. 64.

In interpreting the figures, it must be borne in mind, that, with forty different experiments each year, and, in each year four, five, or more, times, as much produce on some plots as on others, it would be impossible to sample each at its best, and all in the same condition of ripeness. Each year the seed was sown on all the plots at the same time. The sample analysed was in each case a mixture of vertical sections of ten or fifteen roots, and all the samples were as a rule taken within a period of from one to two weeks; as far as practicable beginning with the ripest. It is obvious, however, that the smaller crops would be much riper than the larger ones; but, although the larger crops generally contain a lower percentage of sugar, they yield very much more sugar per acre.

MANURES, PER ACRE, PER ANNUM.

PLOTS.	ABBREVIATED DESCRIPTION OF STANDARD MANURES.	SERIES 1. Standard Manures only.				SERIES 2. Standard Manures, and Cross-dressed with 550 lbs. Nitrate Soda.				SERIES 3. Standard Manures, and Cross-dressed with 400 lbs. Ammonium-salts.				SERIES 4. Standard Manures, and Cross-dressed with 2000 lbs. Rape-cake and 400 lbs. Ammonium-salts.				SERIES 5. (1) For plots 1, 2, and 3, the average percentages of nitrogen are for two years only, 1881 and 1882, as no determinations were made in these plots in 1883 and 1884.

(2) Owing to an accident, the determinations of dry matter were in these cases lost; the means of the percentages of dry matter in the four preceding years are therefore entered in parentheses, and are adopted in the calculation of the percentages of ash and nitrogen, which are also entered in parentheses.

(3) Owing to the failure of the plant on many plots, and the irregularity of the produce for that year is not brought into the average.

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD (after SUGAR-BEET); commencing 1876—continued.

Below are given the particulars of the Manures and Produce, of the Eleventh, Twelfth, Thirteenth, Fourteenth, and Fifteenth seasons, 1886, 1887, 1888, 1889, and 1890. For the Manures and Produce of the 10 preceding seasons see pp. 62-3 and 66-7, and for those of succeeding seasons, pp. 74-5, 78-9, and 82-3.

The arrangement of the plots, and of the Manures, is precisely the same as it was for the ten preceding years of Mangels (see pp. 62-3 and 66-7), and also the same as previously for all carted off; leaves weighed, spread on the respective plots, and ploughed in.

(Area under experiment, about 8 acres.)

8	Unmanured, 1853, and since; previously part Unman., part Superphos.	3 10	0 19	10 18	2 19	6 3	2 13	9 10	3 17	9 15	3 2
9	Farmyard Manure (14 tons), 3½ cwt. Superphosphate (?)	..	..	..	..	16 11	4 19	..	..	..	..

(1) "Superphosphate of Lime," 1886 and 1887, made from 200 lbs. Bone ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water); 1888, and since, made from high percentage mineral phosphates, and containing 37 per cent. or more, of soluble phosphate.

(2) Plot 9 sown on the flat instead of on ridges; plants ridged up afterwards; rows 22 inches apart, plants 10 inches apart in the rows.

(3) 400 lbs. Ammonium-salts, consisting of equal parts of Sulphate and Muriate of Ammonia of Commerce; excepting that for the crop of 1887, 450 lbs. Sulphate Ammonia containing an equal amount of Nitrogen, were applied instead.

(4) Season 1889.—It will be seen that the produce of plots 4, 5, 6, and 7, of Series 2, is entered between parentheses thus (), the amounts being those actually obtained, but owing to a heavy rainfall in July, some of the soil, manure, and plants, were washed away. The produce of roots so lost, is estimated at about 1 ton per acre.

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD—continued.—SUMMARY OF THE COMPOSITION OF THE MANGEL ROOTS, in the Eleventh, Twelfth, Thirteenth, Fourteenth, and Fifteenth Seasons, 1886, 1887, 1888, 1889, and 1890. For particulars of the composition in the first 10 Years, 1876-1885, see pp. 64-5 and 68-9, and for those in succeeding seasons, see pp. 76-7, and 80-1.

An abstract of the analytical results obtained, illustrating the influence of different manures, and of different seasons, on the composition of Mangels, is given below. The dry matter, ash, and nitrogen, are of course determined in the roots themselves. The amounts of dry matter, ash, and nitrogen, have also, in many cases, been determined in the expressed juice; and in some cases the amount of the nitrogen existing as albuminoids has been determined (by Church's method); and in some cases the amount as amides and as nitric acid. It may be observed that by far the larger proportion of both the mineral matter and the nitrogen of the roots is found in the juice; and of the nitrogen in the juice a variable proportion, ranging from less than one-fifth to not more than one-third of the total, is found to exist as albuminoids. When sugar has been estimated, it has been determined in the expressed juice, and calculated into its percentage in the roots, as described in more detail in the letterpress above the Table on p. 64.

(*) 400 lbs. Ammonium-salts, consisting of equal parts of Sulphate and Muriate of Ammonia of Commerce; excepting that for the crop of 1887, 450 lbs. Sulphate Ammonia, containing an equal amount of Nitrogen were applied instead.

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD (after SUGAR-BEET); commencing 1876—continued.

Below are given the particulars of the Manures and Produce, of the Sixteenth, Seventeenth, Eighteenth, Nineteenth, and Twentieth Seasons, 1891, 1892, 1893, 1894, and 1895. For the Manures and Produce of the 15 preceding seasons, see pp. 62-3, 66-7, and 70-1, and for those of succeeding seasons, see pp. 78-9, and 82-3.

The arrangement of the plots, and of the manures, is precisely the same as it was for the fifteen preceding years of Mangels (see pp. 62-3, 66-7, and 70-1), and also the same as previously for Sugar-beet (see pp. 58-9); excepting that Plot 9, which was unmanured for

Sugar-beet, and also previously for Swedes, was brought in as a manured plot for Mangels. With this exception the manures are also substantially the same as previously for Sugar-beet; in fact, precisely the same as for the Sugar-beet in 1872 and 1873. Seed, Yellow Globe; dibbled on ridges; rows 26 inches apart; plants 11 inches apart in the rows. (2) Roots all carted off; leaves weighed, spread on the respective plots, and ploughed in. In the spring of 1894 permanent division paths were laid out between plot and plot.

(Area under experiment, about 8 acres.)

MANURES PER ACRE PER ANNUM.

(¹) Superphosphate of Lime, made from high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate.
 (²) Plot 9 sown on the flat instead of on ridges; plants ridged up afterwards; rows 2½ inches apart, plants 10 inches apart in the rows.
 (³) Sowing the seed, the other half sown broadcast, July 10. Series 3 and Series 4, one-half the Ammonium-salts = 200 lbs. only, applied at the time of sowing the seed, the other half sown broadcast, July 10.
 (⁴) 1892, Series 2, one-half the Nitrate of Soda = 275 lbs. only, applied at the time of sowing the seed, the other half sown broadcast, July 10.
 (⁵) Applied for the first time in 1895.
 (⁶) Owing to very heavy rains in November 1894, flooding the lower parts of the Experimental Mangel Field, and washing soil from the Dung plots, especially on to Plot 3, Series 1, there is no doubt that this result is too high, and possibly also those given for Plots 5 and 6.
 (⁷) The plant failed on these plots owing to drought.
 (⁸) In the case of these plots the averages are given for the five years, though as the details show, there was failure of plant from drought, and scarcely any crop, in 1895.

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD—continued.—SUMMARY OF THE COMPOSITION OF THE MANGEL ROOTS IN THE SIXTEENTH, SEVENTEENTH, EIGHTEENTH, NINETEENTH, AND TWENTIETH SEASONS, 1891, 1892, 1893, 1894, AND 1895.

For particulars of the composition in the first 15 Years, 1876-1890, see pp. 64-5, 68-9, and 72-3, and for those in succeeding seasons, see pp. 80-1.

An abstract of the analytical results obtained, illustrating the influence of different manures, and of different seasons, on the composition of Mangels, is given below. The dry matter, ash, and nitrogen, are of course determined in the roots themselves. The amounts of dry matter, ash, and nitrogen, have also, in many cases, been determined in the expressed juice. In many cases also, the amount of the nitrogen existing as albuminoids has been determined (by Church's method); and in some cases the amount as amides and as nitric acid. It may be observed that by far the larger proportion of both the mineral matter and the nitrogen of the roots is found in the juice; and of the nitrogen in the juice a variable proportion, ranging from less than one-fifth to not more than one-third of the total, is found to exist as albuminoids. In former years when sugar has been estimated, it has been determined by polariscope in the expressed juice, and calculated into its percentage in the roots, as described in more detail in the letterpress above the Table on p. 64. In selected cases of the crops of the twentieth season, 1895, sugar was again determined; not, however, in the expressed juice as formerly, but in both an

aqueous, and in an alcoholic extract of the pulp, and the results given in the Table are the means of the determinations in the aqueous, and in the alcoholic extracts, which agreed very closely, calculated into their percentage in the original root.

In interpreting the figures, it must be borne in mind, that, with forty different experiments each year, and in each year four, five, or more, times, as much produce on some plots as on others, it would be impossible to sample each at its best, and all in the same condition of ripeness. Each year the seed was sown on all the plots at the same time. The sample analysed was in each case a mixture of vertical sections of ten or fifteen roots, and all the samples were as a rule taken within a period of from one to two weeks; as far as practicable beginning with the ripest. It is obvious, however, that the smaller crops would be much riper than the larger ones; but, although the larger crops generally contain a lower percentage of sugar, they yield very much more sugar per acre.

9	Farmyard Manure, & Super. ..	..	..	..	..	..	..	..	..	..

(1) The plant failed on these plots, owing to drought, and hence no particulars of composition are given.

(2) In the case of these plots the averages are for only four years, owing to the failure of the plant from drought in 1895.

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD (after SUGAR-BEET); commencing 1876—continued.

Below are given the particulars of the Manures and Produce, of the Twenty-first, Twenty-second, Twenty-third, Twenty-fourth, and Twenty-fifth Seasons, 1896, 1897, 1898, 1899, and 1900. For the Manures and Produce of the 20 preceding seasons, see pp. 62-3, 66-7, 70-1, and 74-5, and for those of succeeding seasons, see pp. 82-3.

The arrangement of the plots, and of the manures, is substantially the same as it was for the 20 preceding years of Mangels (see pp. 62-3, 66-7, 70-1, and 74-5), and also practically the same as previously for Sugar-beet (see pp. 58-9); excepting that Plot 9, which was unmanured for Sugar-beet, and also previously for Swedes, was

brought in as a manured plot for Mangels. In 1896 and since, however, Basic Slag was substituted for Superphosphate of Lime. Seed, Yellow Globe; dibbled or drilled on ridges; rows 26 inches apart; plants 11 inches apart in the rows in 1897 and previously, but 10 inches only in 1898 and since (?). Roots all carted off; leaves weighed, spread on the respective plots, and ploughed in.

In the spring of 1894 permanent division paths were laid out between plot and plot.

(Area under experiment, about 8 acres.)

(¹) Ammonium-salts, equal parts Sulphate and Muriate of Ammonia of Commerce.

(²) Plot 9 sown on the flat instead of on ridges; plants ridged up afterwards; rows 22 inches apart, plants 10 inches apart in the rows.

(³) Owing to very heavy rains in November, 1894, flooding the lower parts of the Experimental Mangel Field, and washing soil from the Dung Plots, especially on to Plot 3, Series 1, and in a less degree on to Plot 3, Series 2, there is no doubt that these results (as those given in 1895) are too high.

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD.—continued.—SUMMARY OF THE COMPOSITION OF THE MANGEL ROOTS IN THE TWENTY-FIRST, TWENTY-SECOND, TWENTY-THIRD, TWENTY-FOURTH, AND TWENTY-FIFTH SEASONS, 1896, 1897, 1898, 1899, AND 1900.

For particulars of the composition in the first 20 Years, 1876-1895, see pp. 64-5, 68-9, 72-3, and 76-7.

An abstract of the analytical results obtained illustrating the influence of different manures, and of different seasons, on the composition of Mangels, is given below. The dry matter, ash, and nitrogen, are of course determined in the roots themselves. The amounts of dry matter, ash, and nitrogen, have also, in many cases, been determined in the expressed juice. In many cases also, the amount of the nitrogen existing as albuminoids has been determined (by Church's method); and in some the amount as amides and as nitric acid. It may be observed that by far the larger proportion of both the mineral matter and the nitrogen of the roots is found in the juice; and of the nitrogen in the juice a variable proportion, ranging from less than one-fifth to not more than one-third of the total, is found to exist as albuminoids. In former years when sugar has been estimated, it has been determined by polariscope in the expressed juice, and calculated into its percentage in the roots, as described in more detail in the letterpress above the Table on p. 64. In selected cases of the crops of the twentieth, twenty-second, twenty-third, twenty-fourth, and twenty-fifth seasons, 1895, 1897, 1898, 1899, and 1900, sugar was again determined. In each year both in an aqueous, and in an

alcoholic extract of the pulp, and the results given in the Table are the means of these determinations, which agreed very closely, calculated into their percentage in the original root.

In 1898 and 1899 determinations of sugar were also made in the expressed juice, but these results are not included in those given in the Table below.

In interpreting the figures, it must be borne in mind, that, with forty different experiments each year, and in each year four, five, or more, times, as much produce on some plots as on others, it would be impossible to sample each at its best, and all in the same condition of ripeness. Each year the seed was sown on all the plots at the same time. The sample analysed was in each case a mixture of vertical sections of ten or fifteen roots, and all the samples were as ripe. It is obvious, however, that the smaller crops would be much riper than the larger ones; but, although the larger crops generally contain a lower percentage of sugar, they yield very much more sugar per acre.

MANURES, PER ACRE, PER ANNUM.

PLOTS.	ABBREVIATED DESCRIPTION OF STANDARD MANURES.	SERIES 1. Standard Manures only.				SERIES 2. Standard Manures, and Cross-dressed with 550 lbs. Nitrate Soda.				SERIES 3. (1) Averages for 4 years only, 1897-1900.

EXPERIMENTS ON MANGEL WURZEL.—BARN FIELD (after SUGAR-BEET); commencing 1876—continued.

Below are given the particulars of the Manures for the Twenty-sixth Season, 1901. For the Manures and Produce of the 25 preceding seasons, see pp. 62-3, 66-7, 70-1, 74-5, and 78-9.

The arrangement of the plots, and of the manures, is substantially the same as it was for the 25 preceding years of Mangels (see pp. 62-3, 66-7, 70-1, 74-5, and 78-9), and also practically the same as previously for Sugar-beet (see pp. 58-9); excepting that Plot 9, which was unmanured for Sugar-beet, and also previously for Swedes, was brought in as a manured plot for Mangels. In 1896 and since, however, Basic Slag was substituted for Superphosphate of Lime. Seed, Yellow Globe; dibbled or drilled on ridges; rows 26 inches apart; plants 11 inches apart in the rows in 1897 and previously, but 10 inches only in 1898 and since (?). Roots all carted off; leaves weighed, spread on the respective plots, and ploughed in.

In the spring of 1894 permanent division paths were laid out between plot and plot.

(Area under Experiment, about 8 acres.)

(1) Plot 9 sown on the flat instead of on ridges; plants ridged up afterwards; rows 22 inches apart, plants 10 inches apart, in the rows.
(2) "Ammonium-salts" equal parts Sulphate and Muriate of Ammonia. In 1901, the north half of each plot of Series 2 and 3 received instead of "Ammonium-salts" as here stated, Bicarbonate of Ammonia containing an equivalent amount of N. Nitrogen.

EXPERIMENTS ON SUGAR-BEET.—BARN FIELD, ROTHAMSTED.

NEW SERIES—commencing in 1898.

Experiments on the growth of Sugar-beet were made at Rothamsted during 5 consecutive years, 1871-5; for the particulars and results of which see pp. 58-61. For summary, and discussion thereof, see No. 92, pp. 27-41, No. 93, pp. 31-48, and No. 97, in the list of papers of Series I., given at p. 14.

Having regard to the renewed interest taken in the question of the growth of Sugar-beet, and the profitable production of sugar from it, in this country, it was decided in 1898 to make some new experiments at Rothamsted on the subject. A special object was, to obtain, in a greater degree than in the earlier experiments, both fair luxuriance, and at the same time adequate ripening; so as to ensure both high percentage of sugar, and high yield of sugar per acre. It was obviously essential to employ seed of the most approved description at the present time. Accordingly, we wrote to Messrs. Vilmorin & Co., of Paris, who sent us seed of their "*White Green Top Brabant*." Two sets of experiments were made in Barn Field in 1898.

The First Set.—These were conducted on short lengths of land in the valley between Series I. and Series II. of the Mangel plots; and they received, respectively, the same mineral manures as the Mangels. One-third of the length had the mineral manures only; one-third the mineral manures and 2 cwt. of Sulphate of Ammonia per acre; and one-third the mineral manures and 272 lbs. Nitrate of Soda in addition (containing the same amount of Nitrogen as the Sulphate of Ammonia). The rows being in continuation of those of the Mangels, they were necessarily of the same distance apart—26 inches; and the Sugar-beet seed was, as was that of the Mangels, sown on ridges. The Sugar-beet seed was, however, dibbled, and at only 8 inches apart in the rows.

The seed was sown on April 19 and 20 (1898); and the nitrogenous manures were top-dressed on July 11, after which there was scarcely any rain until the 27th and 28th, when nearly an inch fell. In August there was less than half the average fall, and in September less than a quarter the average; whilst in August, and in each month to the end of the year, the temperature was over average. The result was, that the nitrogenous manures showed very little effect. In October, when the crops ought to have been ready to take up, there was a fair amount of rain, and the weather being open and warm, the crops were allowed to stand, to see if there would be more effect from the nitrogenous manures. There proved to be some irregularity of the soils of this set of experiments; and, independently of this, on the one hand, the drought limited luxuriance, whilst on the other, the high temperatures favoured the formation of sugar. The result was, high percentage of sugar in the roots, but, with low amounts of produce, low produce of sugar per acre.

The summary of the results obtained on Plots 4 and 5, given in the Table below, will clearly illustrate the character of the crops, both as to quantity and quality.

In the case of Mangels, the sugar is determined in the roots with little more of trimming than is usual in the field for a feeding crop, and the sugar per acre is calculated on the weight of the crop as carted. In the case of Sugar-beet grown for the manufacture of sugar, however, the sugar is determined in the roots with the crowns trimmed off, and the sugar per acre is calculated on the weight of roots per acre in the cleaned and so trimmed condition. The three upper divisions of the Table show the produce of roots per acre as carted, the weight of leaf, and the proportion of leaf to 1,000 root. The subsequent divisions show the produce per acre of the cleaned and trimmed roots, the percentage of sugar in them, and the sugar per acre in the cleaned and trimmed roots.

The plots having received no nitrogenous manure for many years, the yield with the mineral manure alone was only between 6 and 7 tons per acre; and when trimmed as for sugar, little over 6 tons. With the very restricted action of the nitrogenous manures owing to drought, there was very little increase by the Ammonium-salts, and much less than there should have been by the Nitrate of Soda. It will be seen, however, that there was distinctly more effect from the nitrogenous manures when Basic Slag was used with Potash, Soda, and Magnesia, than with Basic Slag alone. With the restricted growth, but favourable temperature for sugar-formation, the percentage of sugar in the roots was fairly high, averaging more than 14. With the limited produce of roots, the produce of sugar per acre was, on Plot 4, with the full mineral manure alone, 2,031 lb.; with Sulphate of Ammonia added, 2,274 lb.; and with Nitrate of Soda added, 3,524 lb. Thus, therefore, with the plants so wide apart, and with such limited action of the nitrogenous manures owing to season, there was still, with the full mineral manure and Nitrate of Soda, rather more than $1\frac{1}{2}$ ton of sugar per acre.

sugar per acre.

EXPERIMENTS ON SUGAR-BEET.—BARN FIELD, ROTHAMSTED.

NEW SERIES—commencing in 1898.

The Second Set.—This set of experiments was carried out on a portion of Plot 9 of the Mangel-land, which had received Dung and Phosphate, and some Ammonium-salts, for 22 years in succession, 1876-97. Unlike the soil on which the first set was conducted, the soil of this set was, therefore, in high condition, so far as previous treatment was concerned. The land was subsoiled, and received a good deal of extra working, in order to secure a good tilth and seed bed. Mineral manure was applied over the whole on April 6, at the rate of 500 lbs. Sulphate of Potash, and 400 lbs. of Basic Slag per acre. Owing, however, to the additional mechanical operations, and the intervention of rain delaying the working of the land, the seed was not dibbled until May 12, or rather more than three weeks later than the first set. The seed was put in on the flat, in rows 15 inches apart, with 8 inches apart in the rows. One-third of the area had the mineral manures alone; one-third 2 cwts. per acre of Sulphate of Ammonia in addition; and the other third 272 lbs. Nitrate of Soda per acre in addition. As in the case of the first set, the nitrogenous manures were top-dressed on July 11; after which, as has already been explained, there was great deficiency of rain until October, when a fair amount fell; and, as the weather remained open and warm, the crops were allowed to stand, to see if there would be more effect from the nitrogenous manures. There was, in fact, considerable extension of growth of the leaves; but after a time it became a question whether the increased growth of leaf was not in part at the expense of the roots. The weather still remaining favourable, the crops were left standing until the middle of December; but sugar was determined in samples taken on November 22 and 23, and also on December 5 and 6. The results showed, in some cases, a rather lower percentage at the later date; indicating that the increase in the growth of leaves had been, at any rate to some extent, at the expense of the roots. The mean of the results at the two dates is adopted. The Table below gives a summary of the results.

It will be seen that, with the high condition of the land, the produce of roots in 1898 was with mineral manure alone more than 16 tons gross, and nearly 15 tons trimmed—that is about $2\frac{1}{2}$ times as much as in the case of the first set; whilst, owing to the limited action of the nitrogenous manures from drought, there was very little increase of root, but more of leaf, by the addition of these manures. Under these circumstances, the proportion of leaf to 1,000 of root was more than it should be in favourably matured Sugar-beet, and this was the case notwithstanding that the plants were grown so close together. The percentage of sugar in the roots was, therefore, lower than it would have been if the roots had been taken up at their best stage of maturation, that is, before the second growth of leaf. Nevertheless, there was a produce of trimmed roots of about 15 tons per acre; and a yield of sugar per acre in the roots reckoned as cleaned and trimmed, of 4,292 lbs. with the mineral manure alone, 4,365 lbs. with the mineral manure and Sulphate of Ammonia, and 4,402 lbs. with the mineral manure and Nitrate of Soda; that is, nearly 2 tons of sugar per acre.

It was decided not to repeat the first set of experiments—those in the valley between Series I. and Series II. of the Mangels. But those of the second set, under more suitable circumstances as to the condition of the land, and as to distance apart of the plants, are continued. In 1898, the rows were 15 inches apart, but 17 inches in 1899 and since; in each year 8 inches from plant to plant in the rows. The same mineral manures as in 1898 have been applied in each year since.

In 1899, the condition of the land and of the weather being favourable, the same amounts of Sulphate of Ammonia and of Nitrate of Soda were sown, and harrowed in, on May 2, instead of being left for top-dressing later; and the seed was afterwards dibbled, also on May 2, as stated in the Table below. Owing, however, to drought, the plant to a great extent failed, and the blanks were filled in by transplanting; but the growth was restricted from continued deficiency of rain.

In 1900, the nitrogenous manures were top-dressed on July 19, and the season being throughout favourable, there was considerable increase both of roots and of sugar obtained by their use. The percentage of sugar in the roots is seen to be a good deal higher than in 1898, and the produce of sugar per acre was, with the mineral manure alone 4,096 lbs., with Sulphate of Ammonia in addition 5,631 lbs., and with Nitrate of Soda in addition 5,643 lbs.

PLAN OF THE PLOTS IN HOOS FIELD,
ON WHICH EXPERIMENTS HAVE BEEN MADE
ON POTATOES,
WITHOUT MANURE, AND WITH VARIOUS MANURES.

26 years, 1876-1901.

[For a brief summary of results and conclusions, see opposite page.]

Total area of ploughed land about $2\frac{1}{10}$ acre.

Area of each plot $\frac{1}{2}$ acre.

The double lines indicate division paths between plot and plot.

[For details of the manuring and produce, see pp. 88-109.]

RESULTS OF EXPERIMENTS MADE IN HOOS FIELD, ON THE GROWTH OF POTATOES.

These experiments were commenced in 1876, so that 1901 is the 26th year of their continuance. The descriptions grown were "Rock," 4 years, "Champion," 11 years, "Sutton's Abundance," 5 years, "Bruce," 1 year, and "White Beauty of Hebron," 1897, and since. The question was not as to the comparative merits of different descriptions, and different sorts were selected on the supposition that in growing the crop year after year change was desirable, especially with a view to the avoidance or lessening of disease. The special object was to ascertain the manurial requirements of the crop, and the comparative characters and composition of the produce.

The crop was grown continuously without manure, with various artificial manures, and also with farmyard manure, both alone and with some artificial manures. There were 10 differently manured plots, and under each of the 10 conditions the crop more or less declined over the later compared with the earlier years. The average produce per acre of total tubers over the 20 years was—without manure, only 1 ton, 11½ cwt.; with ammonium-salts alone, 1 ton, 18½ cwt.; with nitrate of soda alone, 2 tons, 8 cwt.; with superphosphate alone, 3 tons, 2½ cwt.; with mixed mineral manure, including potash, 3 tons, 6½ cwt. Thus, purely nitrogenous manures yielded less than purely mineral manures, indicating that there was a deficiency of ash-constituents rather than of available nitrogen within the soil. With the mixed mineral manure and ammonium-salts together, the average produce of total tubers was nearly 6 tons, and with the mixed mineral manure and nitrate of soda rather over 6 tons per acre. The better result by the nitrate of soda is doubtless due to its nitrogen being more immediately available, and more rapidly distributed within the soil, and so inducing a more extended development of feeding root. The average produce by the mineral and nitrogenous manures together, over 20 years of continuous growth, was very nearly that of the estimated average produce of Great Britain under ordinary cultivation, and much more than that of Ireland. It was also more than the average of any other country in Europe, much more than many of them, and about 3 times as much as that of the United States.

The plots receiving farmyard manure, containing about 200 lb. of nitrogen, gave less produce than the mixture of mineral manure and ammonium-salts, or nitrate of soda, supplying only 86 lb. of nitrogen. In fact, only a small proportion of the nitrogen of farmyard manure is rapidly available, that due to undigested matter being more slowly available, and that in the litter remaining a long time inactive. Farmyard manure is, however, often applied in very large quantities for potatoes, the process being to a great extent one of forcing, and there remains a great amount of unexhausted manure-residue within the soil.

The percentage of nitrogen in potato tubers is much increased by the application of nitrogenous manures, but the less so the riper the crop. Without manure there is a comparatively low percentage of mineral matter and a medium percentage of nitrogen. With mineral manure alone there is the highest percentage of mineral matter, and the lowest of nitrogen. With purely nitrogenous manures there is the lowest percentage of mineral matter, and the highest of nitrogen. Lastly, with mineral and nitrogenous manures together, there are intermediate percentages, both of mineral matter and of nitrogen, in the tubers. More than 80 per cent. of the total nitrogen of the tubers exists in the juice. A comparatively small but variable proportion of the nitrogen of the tubers exists as albuminoids in the solid portion; perhaps on the average only about 15 per cent.; whilst from 40 to 50 per cent. of the total nitrogen may exist as soluble albuminoids in the juice, so that about or nearly two-thirds of the total nitrogen may exist as albuminoids, by far the larger proportion being, however, in the juice. The non-albuminoid nitrogenous matter exists chiefly as amides.

The characteristic effect of nitrogenous manures, provided there be a sufficient available supply of ash-constituents, and especially of potash, is to increase the amount of the non-nitrogenous substance—starch, in the tubers. Thus, the produce of starch per acre was about 1100 lb. without manure, nearly 2000 lb. with purely mineral manure, and with nitrogenous and mineral manures together about 3400 lb., or about 1½ ton. In other words, the increased produce of starch by the use of the mineral and nitrogenous manures together was more than 1 ton per acre. That is, there was a great increase in the production of the non-nitrogenous constituent—starch, by the use of nitrogen in manure, just as there is an increase in the produce of the non-nitrogenous constituent—sugar, by the use of nitrogenous manures to root crops. The increased production of non-nitrogenous substances by nitrogenous manures, is equally striking in cereal crops; the result in their case being an increased production of starch in the grain, and of cellulose in the straw. Indeed, it is for the production of the non-nitrogenous substances—starch, sugar, and cellulose—that our direct nitrogenous manures are chiefly used.

It is well known that season has much to do with the development of the potato disease; and there was on the average much more disease in the wetter seasons. As regards the influence of manure, the proportion of diseased tubers was the least where there was no supply of nitrogen; that is, where there was the least luxuriance, the most restricted growth, and where the ripening was early developed. On the other hand, with liberal supply of nitrogen, and luxuriant growth, there was the greatest proportion of diseased tubers; these being the conditions in which the juice is relatively rich in nitrogenous and mineral matters. Indeed, when the unsuitable weather comes, those tubers suffer the most which have the richest juice, that is, the least fixity of composition. It was found that there was always a higher, and sometimes a much higher, percentage of nitrogen in the dry substance of the diseased than in that of the sound tubers, indicating a loss of non-nitrogenous constituents. In many cases the still white, and also the separated discoloured portion of the diseased tubers, were analysed. Whilst the juice of the white portion contained approximately the normal amount of nitrogen, that of the discoloured portion contained very much less. On the other hand, the washed "Marc" of the white portion contained very little nitrogen, whilst that of the discoloured portion contained very much more. The distribution of the mineral matter to a great extent followed that of the nitrogen. The juice had obviously suffered exhaustion of much of both its nitrogen and its mineral matter in the development of the fungus. Further, there was more sugar (partly cane and partly glucose) in the diseased potatoes, which probably contributed to the development of the fungus. Apparently the first material change in the development of the disease is the destruction of starch and the formation of sugar. There is also a considerable loss of organic, and chiefly non-nitrogenous substance, due in part to the decomposition of the produced sugar, but probably in part to the evolution of carbonic acid, as a coincident of the growth of the fungus at the expense of ready-formed organic substance, this being a characteristic of the growth of such non-chlorophyllous plants. Thus the results adduced as to the course of the disease are quite consistent with the fact that it develops the more in tubers grown by highly nitrogenous manures, and having a highly nitrogenous juice.

A full available supply of ash-constituents is essential for the successful growth of the potato, but these being provided, the amount of produce is largely dependent on the available supply of nitrogen. In ordinary practice, farmyard manure is mainly relied upon. It is used in very large quantities, and it is sometimes supplemented by liberal dressings of artificial manures, both mineral and nitrogenous. The potato removes, however, a less proportion of the nitrogen supplied than any other farm crop.

For particulars of the manuring and produce, and to some extent of the composition of the differently grown tubers, see pages 88-109.

EXPERIMENTS ON POTATOES.—HOOS FIELD; commencing 1876.

Below are given the particulars of the Manures and Produce of each of the first 5 Seasons, 1876-1880; also the *average* Produce of those first 5 Seasons. For continuation, 1881 and since, see pp. 92-3, 96-7, 100-1, 104-5, and 108-9.

The Land had been under experiments with Wheat, differently manured, from 1856 to 1874; and was fallowed in 1875.

Plots 1, 2, 3, and 4 had been unmanured for the Wheat. Plots 5 and 6 had received the same quantity of Ammonium-salts alone every year for the Wheat, as Plot 5 now receives for potatoes: Plot 6 now receiving the same amount of nitrogen, but as Nitrate of Soda, instead of Ammonium-salts. Plots 7 and 8 received the same amount of complex mineral manure, and Ammonium-salts, for the Wheat, as Plot 7

now receives for potatoes; and Plot 8 now receives the same complex mineral manures, and the same amount of nitrogen, but as Nitrate of Soda instead of Ammonium-salts. Plots 9 and 10 received the same complex mineral manures alone for the Wheat as Plot 10 now receives for potatoes; Plot 9 now receives superphosphate only. (?) Description of Potatoes, in 1876, 1877, 1878, and 1879, the "Rock" (White); and in those years the rows were 25 inches apart; with 12 inches from plant to plant in the rows. In 1880, the description was the "Champion" (White); and the rows were 25 inches apart, with 14 inches from plant to plant in the rows.

(Area under experiment, 2 acres.)

1) "Superphosphate of Lime"—in all cases made from 200 lbs. Bone-ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water).

2) "Ammonium-salts"—in each case equal parts Sulphate and Muriate Ammonia of Commerce.

EXPERIMENTS ON POTATOES.—HOOS FIELD—continued.—SUMMARY OF THE COMPOSITION OF THE "GOOD" TUBERS, in each of the first 5 Seasons, 1876-1880; also the average composition over those first 5 Seasons. For the composition in 1881 and since, see pp. 94-5, 98-9, 102-3, and 106-7.

"mare" of the white portion, contained very little nitrogen, whilst that of the discoloured portion contained very much more. The distribution of the mineral matter was much in the same order as that of the nitrogen. It was obvious that the juice had suffered exhaustion of much of both its nitrogen and its mineral matter, in the development of the fungus. There was an increased amount of sugar found in the diseased potatoes, the result of diseased action, and it probably also contributed to the development of the fungus.

The results given in the Table relate to the "good" potatoes only. In interpreting the figures it must be borne in mind that in each year, the seed was planted on all the plots at the same time, and that all the crops were taken up at the same time; and as there was several times as much produce in some cases as in others, it is obvious that the crops would not each be at its best, and all in the same condition of maturity, when taken up. Then, again, the analyses were performed immediately after taking up the crops, but some time afterwards, in weighed samples which had been kept in a cool place for some weeks or months; and in the following only preliminary statement of results, no correction is made for any change from the original weight of the samples, the results being calculated upon the fresh weights as finally taken for analysis.

An abstract of the analytical results obtained, illustrating the influence of different manures, and of different seasons, on the composition of Potatoes, is given below. The specific gravity of the tubers is also given. In the tubers the dry matter, nitrogen, and ash have been determined; and in some cases complete analyses of the tubers themselves, the dry matter, the results obtained relating to the composition of the tubers, the sugar, the nitrogen, and the ash, in the expressed juice have in many cases been determined; and in some cases the amount of the nitrogen existing as albuminoids has been determined; that in some, complete analyses of the ash of the juice have been made. It may be remarked, that by far the larger proportion of both the mineral matter, and the nitrogen, is found to exist in the juice; and of the nitrogen in the juice, as a rule, not much more than half exists as albuminoids. In the majority of cases, the small potatoes have been submitted to the same methods of analysis as the good potatoes. And in a large number of cases, similar methods of examination have been applied to the still white, and also to the separated discoloured portions of the diseased potatoes. With regard to these latter results, it may be observed, that whilst the juice of the white portion of the diseased potatoes contained approximately the normal amount of nitrogen, that of the discoloured portion contained very much less. On the other hand, the washed, or exhausted

discoloured portion contained very much less

(1) "Superphosphate of Lime"—in all cases made from 200 lbs. Bone-ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water).
(2) "Ammonium-salts"—in each case equal parts Sulphate and Muriate Ammonia of Commerce.

EXPERIMENTS ON POTATOES.—HOOS FIELD—continued.

Below are given the particulars of the Manures and Produce of the Sixth, Seventh, Eighth, Ninth, and Tenth Seasons, 1881, 1882, 1883, 1884, and 1885. For the Manures and Produce of the 5 preceding years, see pp. 88-9, and of succeeding years, 1886 and since, see pp. 96-7, 100-1, 104-5, and 108-9.

The Land had been under experiments with Wheat, differently manured, from 1856 to 1874; and was followed in 1875.

Plots 1, 2, 3, and 4 had been unmanured for the Wheat. Plots 5 and 6 had received the same quantity of Ammonium-salts alone every year for the Wheat, as Plot 5 now receives for potatoes; Plot 6 now receiving the same amount of nitrogen, but as Nitrate of Soda, instead of Ammonium-salts. Plots 7 and 8 received the

same amount of complex mineral manure, and Ammonium-salts, for the Wheat, as Plot 7 now receives for potatoes; and Plot 8 now receives the same complex mineral manures, and the same amount of nitrogen, but as Nitrate of Soda instead of Ammonium-salts. Plots 9 and 10 received the same complex mineral manures alone for the Wheat as Plot 10 now receives for potatoes; Plot 9 now receives superphosphate only. Description of Potatoes, in 1876, 1877, 1878, and 1879, the "Rock" (White); and in those years the rows were 25 inches apart, with 12 inches from plant to plant in the rows. In 1881, 1882, 1883, 1884, and 1885, the description was the "Champion" (White); and the rows were 25 inches apart, with 14 inches from plant to plant in the rows.

(Area under experiment, 2 acres.)

(1) "Superphosphate of Lime"—in all cases made from 200 lbs. Bone-ash, 150 lbs. Sulphuric acid, sp. gr. 1.17 (and water).

(2) "Ammonium-salts"—in each case equal parts Sulphate and Murate Ammonia of Commerce.

EXPERIMENTS ON POTATOES.—HOOS FIELD—continued.—SUMMARY OF THE COMPOSITION OF THE "GOOD" TUBERS, in the Sixth, Seventh, Eighth, Ninth, and Tenth Seasons, 1881, 1882, 1883, 1884, and 1885. For the particulars of the composition in the first 5 years, 1876-1880, see pp. 90-1, and for those in succeeding years, 1886 and since, see pp. 98-9, 102-3, and 106-7.

An abstract of the analytical results obtained, illustrating the influence of different manures, and of different seasons, on the composition of Potatoes, is given below. The specific gravity of the tubers is also given. In the tubers the dry matter, nitrogen, and ash have been determined; and in some cases complete analyses of the ash have been made. Besides the results obtained relating to the composition of the tubers themselves, the dry matter, the sugar, the nitrogen, and the ash, in the expressed juice have in many cases been determined; in some cases the amount of the nitrogen existing as albuminoids has been determined; and in some, complete analyses of both the mineral matter, and the nitrogen, is found to exist in the juice; and of the nitrogen in the juice, as a rule, not much more than half exists as albuminoids. In many cases, the small potatoes have been submitted to the same methods of analysis as the good potatoes. And in some cases, similar methods of examination have been applied to the still white, and also to the separated discoloured portions of the diseased potatoes. With regard to these latter results, it may be observed, that whilst the juice of the white portion of the diseased potatoes contained approximately the normal amount of nitrogen, that of the discoloured portion contained very much less. On the

other hand, the washed, or exhausted "mare" of the white portion, contained very little nitrogen, whilst that of the discoloured portion contained very much more. The distribution of the mineral matter was much in the same order as that of the nitrogen. It was obvious that the juice had suffered exhaustion of much of both its nitrogen and its mineral matter, in the development of the fungus. There was an increased amount of sugar found in the diseased potatoes, the result of diseased action, and it probably also contributed to the development of the fungus.

The results given in the Table relate to the "good" potatoes only. In interpreting the figures it must be borne in mind that in each year, the seed was planted on all the plots at the same time, and that all the crops were taken up at the same time; and as there was several times as much produce in some cases as in others, it is obvious that the crops would not each be at its best, and all in the same condition of maturity when taken up. Then, again, the analyses were not performed immediately after taking up the crops, but sometime afterwards, in weighed samples which had been kept in a cool place for some weeks or months; and in the following only preliminary statement of results, no correction is made for any change from the original weight of the samples, the results being calculated upon the fresh weights as finally taken for analysis.

10	3½ cwt. Superphosphate, 300 lbs. Sulphate Potash, 100 lbs. Sulphate Soda, and 100 lbs. Sulphate Magnesia	1.121	27.8	1.09	3.93	0.238	0.86

(1) "Superphosphate of Lime"—in all cases made from 200 lbs. Bone-ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water).

(2) "Ammonium-salts"—in each case equal parts Sulphate and Murate Ammonia of Commerce.

EXPERIMENTS ON POTATOES.—HOOS FIELD—continued.

Below are given the particulars of the Manures and Produce, of the Eleventh, Twelfth, Thirteenth, Fourteenth, and Fifteenth Seasons, 1886, 1887, 1888, 1889, and 1890. For the Manures, description of Potatoes grown, and the Produce, in the 10 preceding years, see pp. 88-9, and 92-3, and in succeeding years, pp. 100-1, 104-5, and 108-9.

The arrangement of the plots is precisely the same as for the 10 preceding potato crops. The manures are the same as for the crops of 1883, 1884 and 1885, excepting that for the crop of 1887 Sulphate Ammonia was applied instead of equal parts of Sulphate and Muriate Ammonia, as in former years and since (see foot-note No. 2). Description of Potato, "The Champion" (White). Rows 25 inches apart; 14 inches from plant to plant in the rows.

(Area under experiment, 2 acres.)

(') "Superphosphate of Lime," 1886 and 1887, made from 260 lbs. Bone-ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water); 1888, and since, made from high percentage mineral phosphates, and containing 37 per cent. or more, of soluble phosphate.

(') "Ammonium-salts," in each case equal parts Sulphate and Muriate Ammonia of Commerce.

(') 450 lbs. Sulphate Ammonia is estimated to contain the same amount of Nitrogen as the 200 lbs. Sulphate and 200 lbs. Muriate of Ammonia applied in former years, and since.

EXPERIMENTS ON POTATOES.—HOOS FIELD—*continued*.—SUMMARY OF THE COMPOSITION OF THE “GOOD” TUBERS, in the Eleventh, Twelfth, Thirteenth, Fourteenth, and Fifteenth Seasons, 1886, 1887, 1888, 1889, and 1890. For particulars of the composition in the first 10 years, 1876–1885, see pp. 90–1, and 94–5, and for those in succeeding years, 1891 and since, see pp. 102–3, and 106–7.

An abstract of the analytical results obtained illustrating the influence of different manures, and of different seasons, on the composition of Potatoes, is given below. The specific gravity of the tubers is also given. In the tubers the dry matter, nitrogen, and ash have been determined; and in some cases complete analyses of the ash have been made. Besides the results obtained relating to the composition of the tubers themselves, the dry matter, the sugar, the nitrogen, and the ash, in the expressed juice have in many cases been determined; in some cases the amount of the nitrogen existing as albuminoids has been determined; and in some, complete analyses of the ash of the juice have been made. It may be remarked, that by far the larger proportion of both the mineral matter, and the nitrogen, is found to exist in the juice; and of the nitrogen in the juice, as a rule, not much more than half exists as albuminoids. In many cases, the small potatoes have been submitted to the same methods of analysis as the good potatoes. And in some cases, similar methods of examination have been applied to the still white, and also to the separated discoloured portions of the diseased potatoes. With regard to these latter results, it may be observed, that whilst the juice of the white portion of the diseased potatoes contained approximately the normal amount of nitrogen, that of the discoloured portion contained very much less. On the other hand, the

washed, or exhausted “marc” of the white portion, contained very little nitrogen, whilst that of the discoloured portion contained very much more. The distribution of the mineral matter was much in the same order as that of the nitrogen. It was obvious that the juice had suffered exhaustion of much of both its nitrogen and its mineral matter, in the development of the fungus. There was an increased amount of sugar found in the diseased potatoes, the result of diseased action, and it probably also contributed to the development of the fungus.

The results given in the Table relate to the “good” potatoes only. In interpreting the figures it must be borne in mind that in each year, the seed was planted on all the plots at the same time, and that all the crops were taken up at the same time; and as there was several times as much produce in some cases as in others, it is obvious that the crops would not each be at its best, and all in the same condition of maturity when taken up. Then, again, the analyses were not performed immediately after taking up the crops, but sometime afterwards, in weighed samples which had been kept in a cool place for some weeks or months; and in the following only preliminary statement of results, no correction is made for any change from the original weight of the samples, the results being calculated upon the fresh weights as finally taken for analysis.

9	3½ cwt. Superphosphate	1.118	27.5	1.05	3.83	0.360	1.31
10	3½ cwt. Superphosphate, 300 lbs. Sulphate Potash, 100 lbs. Sulphate Soda, and 100 lbs. Sulphate Magnesia	1.115	26.9	1.10	4.08	0.303	1.13

FIFTEENTH SEASON, 1890.

1	Unmanured in 1876, and each year since	1.125	28.9	0.81	2.80	0.381	1.32
2	Unmanured in 1882, and since. Previously Farmyard Manure (14 tons)	1.125	30.0	0.82	2.75	0.380	1.27
3	Farmyard Manure (14 tons) alone 1883 and since; previously 3½ cwt. Superphosphate also (1)	1.117	26.8	1.00	3.75	0.293	1.09
4	Farmyard Manure (14 tons) alone 1883 and since. In 1882, and previously, 3½ cwt. Superphosphate, and in 1881, and previously, 550 lbs. Nitrate of Soda also	1.116	27.5	1.06	3.84	0.284	1.03
5	400 lbs. Ammonium-salts (2)	1.118	28.5	0.81	2.84	0.405	1.42
6	550 lbs. Nitrate of Soda	1.119	28.4	0.82	2.88	0.430	1.51
7	400 lbs. Ammonium-salts, 3½ cwt. Superphos., 300 lbs. Sulph. Potash, 100 lbs. Sulph. Soda, 100 lbs. Sulph. Mag.	1.100	25.6	0.97	3.78	0.369	1.44
8	550 lbs. Nitrate of Soda, 3½ cwt. Superphos., 300 lbs. Sulph. Potash, 100 lbs. Sulph. Soda, 100 lbs. Sulph. Mag.	1.115	27.3	0.98	3.59	0.348	1.27
9	3½ cwt. Superphosphate	1.122	28.7	1.01	3.53	0.298	1.04
10	3½ cwt. Superphosphate, 300 lbs. Sulphate Potash, 100 lbs. Sulphate Soda, and 100 lbs. Sulphate Magnesia	1.121	28.2	1.13	4.00	0.245	0.87

AVERAGE OF 5 SEASONS, 1886, '87, '88, '89, and 1890.

1	Unmanured in 1876, and each year since	1.121	28.4	0.81	2.86	0.400	1.41
2	Unmanured in 1882, and since. Previously Farmyard Manure (14 tons)	1.122	28.6	0.85	2.96	0.393	1.37
3	Farmyard Manure (14 tons) alone 1883 and since; previously 3½ cwt. Superphosphate also (1)	1.110	26.0	1.01	3.91	0.371	1.43
4	Farmyard Manure (14 tons) alone 1883 and since. In 1882, and previously, 3½ cwt. Superphosphate, and in 1881, and previously, 550 lbs. Nitrate of Soda also	1.111	26.3	1.01	3.85	0.366	1.40
5	400 lbs. Ammonium-salts (2)	1.116	27.9	0.79	2.85	0.436	1.57
6	550 lbs. Nitrate of Soda	1.118	27.8	0.79	2.85	0.439	1.58
7	400 lbs. Ammonium-salts, 3½ cwt. Superphos., 300 lbs. Sulph. Potash, 100 lbs. Sulph. Soda, 100 lbs. Sulph. Mag.	1.107	26.2	1.01	3.87	0.377	1.44
8	550 lbs. Nitrate of Soda, 3½ cwt. Superphos., 300 lbs. Sulph. Potash, 100 lbs. Sulph. Soda, 100 lbs. Sulph. Mag.	1.112	26.6	0.98	3.70	0.378	1.42
9	3½ cwt. Superphosphate	1.119	27.8	1.04	3.74	0.335	1.20
10	3½ cwt. Superphosphate, 300 lbs. Sulphate Potash, 100 lbs. Sulphate Soda, and 100 lbs. Sulphate Magnesia	1.116	27.3	1.11	4.06	0.303	1.11

(1) "Superphosphate of Lime," 1886 and 1887, made from 200 lbs. Bone-ash, 150 lbs. Sulphuric acid, sp. gr. 1.7 (and water); 1888, and since, made from high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate.

(2) 450 lbs. Sulphate Ammonia is estimated to contain the same amount of Nitrogen as the 200 lbs. Sulphate and 200 lbs. Murate of Ammonia applied in former years, and since.

(100)

EXPERIMENTS ON POTATOES.—HOOS FIELD—continued.

Below are given the particulars of the Manures and Produce, for the Sixteenth, Seventeenth, Eighteenth, Nineteenth, and Twentieth Seasons, 1891, 1892, 1893, 1894, and 1895. For the Manures, description of Potatoes grown, and the Produce, of the 15 preceding years, see pp. 88-9, 92-3, and 96-7; and of the succeeding years, pp. 104-5, and 108-9.

The manures are the same as for the crops of 1883, and since. Description of Potato, "Sutton's Abundance" (White). Rows 25 inches apart; 14 inches from plant to plant in the rows.

In the spring of 1894 permanent division paths were laid out between plot and plot.

The arrangement of the plots is precisely the same as for the 15 preceding potato crops. (Area under experiment, 2 acres.)

(1) "Superphosphate of Lime," made from high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate.
 (2) "Ammonium-salts"—in each case equal parts Sulphate and Muriate Ammonia of Commerce.

EXPERIMENTS ON POTATOES.—HOOS FIELD—continued.—SUMMARY OF THE COMPOSITION OF THE "GOOD" TUBERS IN THE SIXTEENTH, SEVENTEENTH, EIGHTEENTH, NINETEENTH, AND TWENTIETH SEASONS, 1891, 1892, 1893, 1894, AND 1895. For particulars of the composition in the first 15 years, 1876-1890, see pp. 90-1, 94-5, and 98-9, and for those in succeeding seasons, see pp. 106-7.

An abstract of the analytical results obtained, illustrating the influence of different manures, and of different seasons, on the composition of Potatoes, is given below. The specific gravity of the tubers is also given. In the tubers the dry matter, nitrogen, and ash have been determined; and in some cases complete analyses of the ash have been made. Besides the results obtained relating to the composition of the tubers themselves, the dry matter, the sugar, the nitrogen, and the ash, in the expressed juice have in many cases been determined; in some cases the amount of the nitrogen existing as albuminoids has been determined; and in some, complete analyses of the ash of the juice have been made. It may be remarked, that by far the larger proportion of both the mineral matter, and the nitrogen, is found to exist in the juice; and of the nitrogen in the juice, as a rule, not much more than half exists as albuminoids. In many cases, the small potatoes have been submitted to the same methods of analysis as the good potatoes. And in some cases, similar methods of examination have been applied to the still white, and also to the separated discoloured portions of the diseased potatoes. With regard to these latter results, it may be observed, that whilst the juice of the white portion of the diseased potatoes contained approximately the normal amount of nitrogen, that of the discoloured portion contained very much less. On the other hand, the washed or exhausted "marc" of the white portion,

contained very little nitrogen, whilst that of the discoloured portion contained very much more. The distribution of the mineral matter was much in the same order as that of the nitrogen. It was obvious that the juice had suffered exhaustion of much of both its nitrogen and its mineral matter, in the development of the fungus. There was an increased amount of sugar found in the diseased potatoes, the result of diseased action, and it probably also contributed to the development of the fungus.

The results given in the Table relate to the "good" potatoes only. In interpreting the figures it must be borne in mind that in each year, the seed was planted on all the plots at the same time, and that all the crops were taken up at the same time; and as there were several times as much produce in some cases as in others, it is obvious that the crops would not each be at its best, and all in the same condition of maturity when taken up. Then, again, the analyses were not performed immediately after taking up the crops, but some time afterwards, in weighed samples which had been kept in a cool place for some weeks or months; and in the following only preliminary statement of results, no correction is made for any change from the original weight of the samples, the results being calculated upon the fresh weights as finally taken for analysis.

EXPERIMENTS ON POTATOES.—HOOS FIELD—continued.

Below are given the particulars of the Manures and Produce, for the Twenty-first, Twenty-second, Twenty-third, and Twenty-fifth Seasons, 1896, 1897, 1898, 1899 and 1900. For the Manures, description of Potatoes grown, and the Produce, of the 20 preceding years, see pp. 88-9, 92-3, 96-7, and 100-1, and of the succeeding years, pp. 108-9.

The manures are the same as for the crops of 1883, and since; excepting that for the crops of 1897, and since, Basic Slag has been used instead of Superphosphate. Description of Potato, in 1896, "Bruce" (White); in 1897, and since, "Beauty of Hebron" (White). Rows 25 inches apart; 14 inches from plant to plant in the rows. In the spring of 1894 permanent division paths were laid out between plot and plot.

The arrangement of the plots is precisely the same as for the 20 preceding potato crops.

(Area under experiment, 2 acres.)

Withered, not weighed, each lot spread on its own Plot and ploughed in.

(¹) "Superphosphate of Lime," made from high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate.
(²) "Ammonium-salts" — In each case equal parts Sulphate and Murate Ammonia of Commerce.

EXPERIMENTS ON POTATOES.—HOOS FIELD—continued.—SUMMARY OF THE COMPOSITION OF THE "GOOD" TUBERS IN THE TWENTY-FIRST, TWENTY-SECOND, TWENTY-THIRD, TWENTY-FOURTH, AND TWENTY-FIFTH SEASONS, 1896, 1897, 1898, 1899, AND 1900. For particulars of the composition in the first second, Twenty-third, Twenty-fourth, and Twenty-fifth seasons, see pp. 90-1, 94-5, 98-9, and 102-3.

An abstract of the analytical results obtained, illustrating the influence of different manures, and of different seasons, on the composition of Potatoes, is given below. The specific gravity of the tubers is also given. In the tubers the dry matter, nitrogen, and ash have been determined; and in some cases complete analyses of the ash have been made. Besides the results obtained relating to the composition of the tubers themselves, the dry matter, the sugar, the nitrogen, and the ash, in the expressed juice have in many cases been determined; in some cases the amount of the nitrogen existing as albuminoids has been determined; and in some, complete analyses of the ash of the juice have been made. It may be remarked, that by far the larger proportion of both the mineral matter, and the nitrogen, is found to exist in the juice; and of the nitrogen in the juice, as a rule, not much more than half exists as albuminoids. In many cases, the small potatoes have been submitted to the same methods of analysis as the good potatoes. And in some cases, similar methods of examination have been applied to the still white, and also to the separated discoloured portions of the diseased potatoes. With regard to these latter results, it may be observed, that whilst the juice of the white portion of the diseased potatoes contained approximately the normal amount of nitrogen, that of the discoloured portion contained very much less. On the other hand, the washed or exhausted "marc" of the white portion,

contained very little nitrogen, whilst that of the discoloured portion contained very much more. The distribution of the mineral matter was much in the same order as that of the nitrogen. It was obvious that the juice had suffered exhaustion of much of both its nitrogen and its mineral matter, in the development of the fungus. There was an increased amount of sugar found in the diseased potatoes, the result of diseased action, and it probably also contributed to the development of the fungus.

The results given in the Table relate to the "good" potatoes only. In interpreting the figures it must be borne in mind that in each year, the seed was planted on all the plots at the same time, and that all the crops were taken up at the same time; and as there was several times as much produce in some cases as in others, it is obvious that the crops would not each be at its best, and all in the same condition of maturity when taken up. Then, again, the analyses were not performed immediately after taking up the crops, but some time afterwards, in weighed samples which had been kept in a cool place for some weeks or months; and in the following only preliminary statement of results, no correction is made for any change from the original weight of the samples, the results being calculated upon the fresh weights as finally taken for analysis.

PLAN OF THE PLOTS IN AGDELL FIELD,
ON WHICH EXPERIMENTS HAVE BEEN MADE
ON FOUR-COURSE ROTATION.

54 years, commencing 1848.

[For a brief summary of results and conclusions, see opposite page.]

Total area of ploughed land about 3 acres.
Area of each of the 12 divisions $\frac{1}{2}$ acre.

The 4 lower divisions, Unmanured continuously (Plot 1).

The 4 middle divisions, Mineral Manure, for the Roots, each Course (Plot 2).

The 4 upper divisions, Mineral and Nitrogenous Manure, for the Roots, each Course (Plot 3).

The 6 left-hand divisions, Clover (or Beans), 3rd year each Course.

The 6 right-hand divisions, Fallow, 3rd year each Course.

The double lines indicate division paths between plot and plot.

[For details of the manuring and produce, see pp. 112-121.]

RESULTS OF EXPERIMENTS MADE IN AGDELL FIELD, ON
THE ROTATION OF CROPS.

The experiments were commenced in 1848; so that 1901 is the 54th year of their continuance, and the second year of the 14th Course. In the experiments in other fields, some of the most important crops of rotation have been grown, each separately, for many years in succession—without manure, with farmyard manure, and with various artificial manures. But besides such experiments, others have been made on the growth of the crops in an actual course of rotation, without manure, and with different manures. The results with the individual crops throw much light on the characteristic requirements of each particular crop; whilst those on the growth of the crops in rotation serve to confirm and control those with the individual crops.

The rotation selected for investigation was the well known and typical four-course rotation of—1. Turnips; 2. Barley; 3. Leguminous Crops (or Fallow); 4. Wheat; that is, an alternation of Root-crops and of Leguminous Crops with cereals; which is the basis of most of the various rotations adopted in different parts of our own country, and also in many other countries. One portion of the land was left entirely without manure each course; another received mineral manure only, for the turnips of each course; and a third mixed mineral and nitrogenous manures, also only for the turnips of each course.

1. *The Swedish Turnips commencing each Course.*—When various root-crops were grown year after year on the same land without manure, they soon reverted to the uncultivated condition; and the experiments on rotation show that the Swedish turnips grown once in four years in unmanured rotation, came down to only about 1 ton per acre. The results further show, that mineral manures alone applied for the root-crops gave considerable increase, but that mineral and nitrogenous manures together gave more still. Without manure, the average produce of roots was less over the last 4 than over the preceding 8 courses; but with mineral manure alone (including potash in the last 4 courses) it was higher, and with mineral and nitrogenous manures together much higher, over the last 4 courses; the result being, however, largely due to more favourable seasons. Indeed, in 1888 and 1892, the years of root-crop in the 11th and 12th courses, although the produce without manure was less, that by each of the two descriptions of manure was considerably more than the average of the preceding courses; that is, both the reversion to the uncultivated condition without manure, and the increased growth with suitable manures, were very marked. In fact, without manure the produce of roots was as restricted in rotation as in continuous growth; with purely mineral manure it was greater in rotation than in continuous growth, the exhaustion of the available nitrogen of the soil being less under rotation; and with the mixed mineral and nitrogenous manure much more produce was obtained under rotation than with continuous growth. Lastly, the results conclusively show how artificial a product is the cultivated root-crop, and how dependent it is for its successful growth on an abundant supply of available food—nitrogenous as well as mineral—within the soil.

2. *The Barley Crops.*—Barley, without manure, succeeded the differently manured Swedish turnip crops of each course. Although the average produce of the root-crops was greater over the last 4 (10th, 11th, 12th, and 13th) than over the preceding 8 courses, the succeeding barley crops were much less over the last 4 courses. This was the case, not only where the root-crops had been carted off, but also where they had not been so removed. As, however, the produce of barley in the 4 years in question (1885, 1889, 1893, and 1897) was also less than the average in Hoos Field where the crop is grown year after year, the result is doubtless mainly due to the seasons. Then, the average produce of barley over the 8 courses was actually less after the carted off roots grown by mineral manure (super-phosphate) than after those grown without manure. The explanation is—that as there was practically no produce of roots without manure the unmanured plot was practically fallow for the barley; whilst with the mineral manure fair crops of roots were grown and removed, leaving the surface soil the more exhausted of its available nitrogen and other constituents. In the later years, however, after such long continued exhaustion, the unmanured plot has yielded less barley after the removal of the roots than the mineral manured plot. On the other hand, where the roots were not removed from the land, the mineral manured plot has generally yielded more barley than the unmanured. Further, under all conditions of treatment, the plots with mixed mineral and nitrogenous manure have yielded more barley than those with the mineral manure alone. In fact, the effects of the manurial and other treatment of the first crop of the course are clearly manifested in the produce of the second crop. Lastly, both without manure, and with the mineral manure alone, there was more produce of barley in rotation than in continuous growth, but with mixed mineral and nitrogenous manure there was more produce when the crop was grown continuously, the supply of nitrogen in that case being somewhat larger and annually applied for the crop.

3. *The Leguminous Crops (or Fallow).*—Under equal conditions as to manuring, the Leguminous crops, especially the clover, bring much more nitrogen into the course than either of the other crops. Further, the amount of nitrogen so brought into the rotation is much greater under the influence of mineral manures, and especially of potash manures, than without manure; whilst under the influence of the mixed mineral and nitrogenous manure the yield of nitrogen is greater still, the leguminous crop utilising the unexhausted nitrogenous manure- and crop-residue. For the successful growth of leguminous crops, however, a liberal supply of available mineral constituents within the soil, especially potash and lime, is essential. Judging from comparable cases, the amount of nitrogen accumulated by the Leguminous crops was much greater when they were grown in rotation, that is only occasionally, than when grown continuously. With fallow instead of a Leguminous crop, there is very much less nitrogen yielded in the rotation, and more liability to loss of it by drainage, and hence so much less brought into the circulation of the farm for food or manure. Lastly, most of the nitrogen of the leguminous crop is retained on the farm; and there is more or less, and sometimes much nitrogenous crop-residue left in the soil for succeeding crops.

4. *The Wheat Crops.*—There was very much more produce of wheat both without manure and with mineral manure, and considerably more with the mineral and nitrogenous manure, when it was grown in rotation than under comparable conditions continuously. Taking the quantities of produce by the mixed mineral and nitrogenous manure the result was that the two cereal crops produced approximately equal amounts of dry substance, and each considerably more than either of the assumed restorative crops—the roots or the leguminous crops. The supply of nitrogen within the soil available to the wheat crop is increased both by fallow and by the growth of a leguminous crop, especially of clover; and the accumulation is the greater when the soil and subsoil are not abnormally exhausted of organic nitrogen.

Upon the whole the results show that the benefits of rotation are very various. They depend on the varying requirements, habits of growth, and capabilities of gathering and assimilating the necessary constituents, of the different crops. The difference in the amounts available within the soil of the various mineral constituents, is one element in the explanation; but the facts relating to the amount, and to the sources, of the nitrogen of the different crops, are of still greater significance. The uses of the different crops have also to be taken into account. The cereals yield more produce for sale in the season of growth in rotation than when grown continuously. The crops alternated with them accumulate very much more of mineral constituents and of nitrogen in their produce; but by far the greater proportion of those constituents remains in circulation in the manure of the farm, whilst the remainder yields highly valuable products for sale in meat and milk. Again, with a variety of crops, the operations of the farm are better distributed over the year, and are therefore more economically performed. Lastly, the opportunities which alternate cropping affords for cleaning the land constitute a prominent element of advantage.

For details of the manuring and produce of the different plots, see pages 112–121.

AGDELL FIELD.

(Area under experiment, about 3 acres.)

EXPERIMENTS ON AN ACTUAL COURSE OF ROTATION—TURNIPS, BARLEY, LEGUMINOUS CROP (OR FALLOW), AND WHEAT.

These Experiments were commenced in 1848; so that the present season (1901) is the 54th, and the growing crop (Barley) is the second of the Fourteenth Course.

One-third of the land has been continuously unmanured. One-third has, for the first Nine Courses, or 36 years, 1848-83, been manured with Superphosphate of Lime alone, once every four years, that is for the turnip-crop commencing each course; but for the Tenth, Eleventh, Twelfth, Thirteenth, and Fourteenth Courses, a complex mineral manure has been applied, as described in footnote, No. 2. Lastly, one-third has been manured also for the turnip-crop only, with a complex mineral and Nitrogenous manure, as described in the footnote No. 3.

From half of each of the three differently manured plots the turnip-crops (roots and leaves) are removed; and on the other half they are either consumed on the land by sheep, or spread and ploughed in. In the case of all the other crops, the total produce is removed from the land.

In the First Course, clover was sown over the whole of the three differently manured

plots; but in each of the subsequent courses, a leguminous crop was grown on only half of each of the three plots, the other half being left fallow, in the third year of each course. In the Second, Third, and Fourth Courses, clover was sown, but failed; and in them, and in the Fifth and Sixth Courses, beans were taken instead. In the Seventh Course, clover was sown (spring 1873), and gave three cuttings in 1874. In the Eighth Course beans were grown. In the Ninth Course clover was sown (in the spring of 1881), and gave two cuttings in 1882. In the Tenth Course clover was sown (in the spring of 1885), and yielded two cuttings in 1886. In the Eleventh Course clover was sown (with the barley) in 1889, but failed during the winter, and in 1890 beans were grown instead. In the Twelfth Course clover was again sown in April 1893, and gave two cuttings in 1894. In the Thirteenth Course clover was sown (with the barley), April 1897, but failed during the winter, and in 1898 beans were grown instead. In the Fourteenth Course clover was sown (with the barley), May 4, 1901.

TABLE I. (below), gives the results relating to the portions of each plot from which the turnip-crops were entirely removed; and on which clover or beans were grown.

Years.	Description of Crop.	PRODUCE PER ACRE.											
		Plot 1. Unmanured continuously.					Plot 2. Superphosphate of Lime alone (1), Courses 1-9, Complex Mineral Manure (2), Courses 10-14, for the Turnip Crops only.					Plot 3. Complex Mineral and Nitrogenous Manure, (3) for the Turnip Crops only.

(1) First Course—100 lbs. Bone-ash, and 100 lbs. Sulphuric Acid (sp. gr. 1.7); Second Course—160 lbs. Bone-ash, 120 lbs. Sulphuric Acid; Third, Fourth, Fifth, Sixth, Seventh, Eighth, Ninth, and Tenth Courses—made from high percentage mineral phosphate, and containing 37 per cent., or more, of soluble phosphate.

(2) For the Tenth Course, in addition to the Superphosphate for the Swedish Turnips—300 lbs. Sulphate of Potash, 200 lbs. Sulphate of Soda, and 100 lbs. Sulphate of Ammonia were applied February 23, 1894, and harrowed in; and the same quantities were applied again before the final ploughing and preparation of the land for the sowing of the seed in May. For the Swedish of the Eleventh and Twelfth Courses the same mineral manures (which are the same as the mineral manures of Plot 3 for the third and subsequent Courses) were again applied, but only once for each of these two Courses. For the Swedish of the Thirteenth and Fourteenth Courses—500 lbs. Sulphate of Potash, 100 lbs. Sulphate of Soda, 200 lbs. Sulphate of Ammonia, and 600 lbs. Basic Slag, per acre.

(3) First Course—100 lbs. Bone-ash, 100 lbs. Sulphuric Acid, 100 lbs. Sulphate of Ammonia,

100 lbs. Muriate of Ammonia, and 1000 lbs. Rape Cake; Second Course—300 lbs. Sulphate of Potash, 100 lbs. Sulphate of Soda, 100 lbs. Sulphate of Ammonia, 120 lbs. Bone-ash, 120 lbs. Sulphuric Acid, 100 lbs. Sulphate of Ammonia, 100 lbs. Muriate of Ammonia, and 2000 lbs. Rape-cake; Third, Fourth, Fifth, Sixth, Seventh, Eighth, Ninth, and Tenth Courses—300 lbs. Sulphate of Potash, 200 lbs. Sulphate of Ammonia, 100 lbs. Sulphate of Soda, 100 lbs. Muriate of Ammonia, and 2000 lbs. Rape-cake, per acre; Eleventh and Twelfth Courses—the same in other respects as in Courses 3-10, but the Superphosphate made from high percentage mineral phosphate, and containing 37 per cent., or more, of soluble phosphate. For the Swedish of the Thirteenth and Fourteenth Courses—500 lbs. Sulphate of Potash, 100 lbs. Sulphate of Soda, 200 lbs. Sulphate of Ammonia, 600 lbs. Basic Slag, 2000 lbs. Rape-cake, 100 lbs. Sulphate of Ammonia, and 100 lbs. Muriate of Ammonia, per acre. (4) The quantities given in *Swedes* represent the *Dressed Corn* only. (5) Two cuttings. (6) Three cuttings.

[For Summary Table of the above results, see pp. 120-121.]

A G D E L L F I E L D.

(Area under experiment, about 3 acres.)

EXPERIMENTS ON AN ACTUAL COURSE OF ROTATION—TURNIPS, BARLEY, LEGUMINOUS CROP (OR FALLOW), AND WHEAT.

These Experiments were commenced in 1848; so that the present season, 1901, is the 54th, and the growing crop (Barley) is the second of the Fourteenth Course.

One-third of the land has been continuously unmanured. One-third has, for the first Nine Courses, or 36 years, 1848-83, been manured with Superphosphate of Lime alone, once every four years, that is for the turnip-crop commencing each course; but for the Tenth, Eleventh, Twelfth, Thirteenth, and Fourteenth Courses, a complex mineral manure has been applied, as described in foot-note, No. 2. Lastly, one-third has been manured (also for the turnip-crop only), with a complex mineral and Nitrogenous manure, as described in the foot-note, No. 3.

From half of each of the three differently manured plots, the turnip-crops (roots and leaves) are removed; and on the other half they are either consumed on the land by sheep, or spread and ploughed in. In the case of all the other crops, the total produce is removed from the land.

In the First Course, clover was sown over the whole of each of the three differently manured

plots; but in each of the subsequent courses, a leguminous crop was grown on only half of each of the three plots, the other half being left fallow, in the third year of each course. In the Second, Third, and Fourth Courses, clover was sown, but failed; and in them, and in the Fifth and Sixth Courses, beans were taken instead. In the Seventh Course, clover was sown (spring 1873), and gave three cuttings in 1874. In the Eighth Course beans were grown. In the Ninth Course clover was sown (in the spring of 1881), and gave two cuttings in 1882. In the Tenth Course clover was sown (in the spring of 1885), and yielded two cuttings in 1886. In the Eleventh Course clover was sown (with the barley), in 1889, but failed during the winter, and in 1890 beans were grown instead. In the Twelfth Course clover was again sown in April 1893, and gave two cuttings in 1894. In the Thirteenth Course clover was sown (with the barley), April 1897, but failed during the winter, and in 1898 beans were grown instead. In the Fourteenth Course clover was sown (with the barley), May 4, 1901.

TABLE II. (below), gives the results relating to the portions of each plot from which the turnip-crops were entirely removed; and on which, in the third year of each course (excepting the first, 1850, when clover was grown), the land was left fallow.

Years.	Description of Crop.	PRODUCE PER ACRE.											
		Plot 1. Unmanured continuously.				Plot 2. Superphosphate of Lime alone (1), Courses 1-9, Complex Mineral Manure (2), Courses 10-14, for the Turnip Crops only.				Plot 3. Complex Mineral and Nitrogenous Manure (3), for the Turnip Crops only.

(1) First Course—100 lbs. Bone-ash, and 100 lbs. Sulphuric Acid (sp. gr. 1.7); Second Course—160 lbs. Bone-ash, 120 lbs. Sulphuric Acid; Third, Fourth, Fifth, Sixth, Seventh, Eighth, Ninth, and Tenth Courses—200 lbs. Bone-ash, and 150 lbs. Sulphuric Acid, per acre; Eleventh and Twelfth Courses—made from high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate.

(2) For the Tenth Course, in addition to the Superphosphate for the Swedish Turnips—300 lbs. Sulphate of Potash, 200 lbs. Sulphate of Soda, and 100 lbs. Sulphate of Magnesia were applied February 29, 1884, and harrowed in; and the same quantities were applied again before the final ploughing and preparation of the land for the sowing of the seed in May. For the Swedes of the Eleventh and Twelfth Courses the same mineral manures (which are the same as the mineral manures of Plot 3 for the Third and subsequent Courses) were again applied, but only once for each of these two Courses. For the Swedes of the Thirteenth and Fourteenth Courses—500 lbs. Sulphate of Potash, 100 lbs. Sulphate of Soda, 200 lbs. Sulphate of Magnesia, and 600 lbs. Basic Slag, per acre.

(3) First Course—100 lbs. Bone-ash, 100 lbs. Sulphuric Acid, 100 lbs. Sulphate of Ammonia,

100 lbs. Muriate of Ammonia, and 1000 lbs. Rape-cake; Second Course—300 lbs. Sulphate of Potash, 100 lbs. Sulphate of Soda, 100 lbs. Sulphate of Magnesia, 100 lbs. Bone-ash, 120 lbs. Sulphuric Acid, 100 lbs. Sulphate of Ammonia, 100 lbs. Muriate of Ammonia, and 2000 lbs. Rape-cake; Third, Fourth, Fifth, Sixth, Seventh, Eighth, Ninth, and Tenth Courses—300 lbs. Sulphate of Potash, 200 lbs. Sulphate of Soda, 100 lbs. Sulphate of Magnesia, 200 lbs. Bone-ash, 150 lbs. Sulphuric Acid, 100 lbs. Sulphate of Ammonia, 100 lbs. Muriate of Ammonia, and 2000 lbs. Rape-cake, per acre; Eleventh and Twelfth Courses—the same in other respects as in Courses 3-10, but the Superphosphate made from high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate. For the Swedes of the Thirteenth and Fourteenth Courses—500 lbs. Sulphate of Potash, 100 lbs. Sulphate of Soda, 200 lbs. Sulphate of Magnesia, 600 lbs. Basic Slag, 2000 lbs. Rape-cake, 100 lbs. Sulphate of Ammonia, and 100 lbs. Muriate of Ammonia, per acre.

(4) The quantities given in *Bushels* represent the *Dressed Corn* only.

(5) The "Total Produce" of the Corn-crops includes Dressed Corn, Offal Corn, Straw, and Chaff.

(6) Two cuttings.

[For Summary Table of the above results, see pp. 120-121.]

AGDELL FIELD.

(Area under experiment, about 3 acres.)

EXPERIMENTS ON AN ACTUAL COURSE OF ROTATION—TURNIPS, BARLEY, LEGUMINOUS CROP (OR FALLOW), AND WHEAT.

These Experiments were commenced in 1848; so that the present season, 1901, is the 54th, and the growing crop (Barley) is the second of the Fourteenth Course. One-third of the land has been continuously unmanured. One-third has, for the first Nine Courses, or 36 years, 1848-83, been manured with Superphosphate of Lime alone, once every four years, that is, for the turnip-crop commencing each course; but for the Tenth, Eleventh, Twelfth, Thirteenth, and Fourteenth Courses, a complex mineral manure has been applied, as described in foot-note, No. 2. Lastly, one-third has been manured (also for the turnip-crop only), with a complex mineral and Nitrogenous manure, as described in the foot-note, No. 3. From half of each of the three differently manured plots, the turnip-crops (roots and leaves) are removed; and on the other half they are either consumed on the land by sheep, or spread and ploughed in. In the case of all the other crops, the total produce is removed from the land. In the First Course, clover was sown over the whole of each of the three differently manured plots; but in each of the subsequent courses a leguminous crop was grown on only half of each of the three plots, the other half being left fallow, in the third year of each course. In the Second, Third, and Fourth Courses, clover was sown, but failed; and in them, and in the Fifth and Sixth Courses, beans were taken instead. In the Seventh Course, clover was sown (spring 1873), and gave three cuttings in 1874. In the Eighth Course beans were grown. In the Ninth Course clover was sown (in the spring of 1881), and gave two cuttings in 1882. In the Tenth Course clover was sown (in the spring of 1885), and yielded two cuttings in 1886. In the Eleventh Course clover was sown (with the barley) in 1889, but failed during the winter, and in 1890 beans were grown instead. In the Twelfth Course clover was again sown in April 1893, and gave two cuttings in 1894. In the Thirteenth Course clover was sown (with the barley), April 1897, but failed during the winter, and in 1898 beans were grown instead. In the Fourteenth Course clover was sown (with the barley), May 4, 1901.

TABLE III. (below), gives the results relating to the portions of each plot on which the turnip-crops were either fed off by sheep, or cut and spread on the land; and on which clover or beans were grown.

AGDELL FIELD.

(Area under experiment, about 3 acres.)

EXPERIMENTS ON AN ACTUAL COURSE OF ROTATION—TURNIPS, BARLEY, LEGUMINOUS CROP (OR FALLOW), AND WHEAT.

These Experiments were commenced in 1843; so that the present season, 1901, is the 54th, and the growing crop (Barley) is the second of the Fourteenth Course.
One-third of the land has been continuously unmanured. One-third has, for the first Nine Courses, or 36 years, 1843-83, been manured with Superphosphate of Lime alone, once every four years, that is for the turnip-crop commencing each course; but for the Tenth, Eleventh, Twelfth, Thirteenth, and Fourteenth Courses, a complex mineral manure has been applied, as described in foot-note, No. 2. Lastly, one-third has been manured (also for the turnip-crop only), with a complex mineral and Nitrogenous manure, as described in the foot-note, No. 3.

From half of each of the three differently manured plots, the turnip-crops (roots and leaves) are removed; and on the other half they are either consumed on the land by sheep, or spread and ploughed in. In the case of all the other crops, the total produce is removed from the land.

In the First Course, clover was sown over the whole of each of the three differently manured

plots; but in each of the subsequent courses, a leguminous crop was grown on only half of each of the three plots, the other half being left fallow, in the third year of each course. In the Second, Third, and Fourth Courses, clover was sown, but failed; and in them, and in the Fifth and Sixth Courses, beans were taken instead. In the Seventh Course, clover was sown (spring 1875), and gave three cuttings in 1874. In the Eighth Course beans were grown. In the Ninth Course clover was sown (in the spring of 1881), and gave two cuttings in 1882. In the Tenth Course clover was sown (in the spring of 1885), and yielded two cuttings in 1886. In the Eleventh Course clover was sown (with the barley), in 1889, but failed during the winter, and in 1890 beans were grown instead. In the Twelfth Course clover was again sown in April 1893, and gave two cuttings in 1894. In the Thirteenth Course clover was sown (with the barley), April 1897, but failed during the winter, and in 1898 beans were grown instead. In the Fourteenth Course clover was sown (with the barley), May 4, 1901.

TABLE IV. (below), gives the results relating to the portions of each plot on which the turnip-crops were either fed off by sheep, or cut and spread on the land; and on which, in the third year of each course (excepting the first, 1850, when clover was grown), the land was left fallow.

Years.	Description of Crop.	PRODUCE PER ACRE.

1903		Wheat									

(1) First Course—100 lbs. Bone-ash, and 100 lbs. Sulphuric Acid (sp. gr. 1.7); Second Course—1600 lbs. Bone-ash, 120 lbs. Sulphuric Acid; Third, Fourth, Fifth, Sixth, Seventh, Eighth, Ninth, and Tenth Courses—200 lbs. Bone-ash, and 150 lbs. Sulphuric Acid, per acre; Eleventh and Twelfth Courses—made from high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate.

(2) For the Tenth Course, in addition to the Superphosphate for the Swedish Turnips—300 lbs. Sulphate Potash, 200 lbs. Sulphate Soda, and 100 lbs. Sulphate Magnesia were applied February 29, 1884, and harrowed in; and the same quantities were applied again before the final ploughing and preparation of the land for the sowing of the seed in May. For the Swedes of the Eleventh and Twelfth Courses the same mineral manures (which are the same as the mineral manures of Plot 3 for the Third and subsequent Courses) were again applied, but only once for each of these two Courses. For the Swedes of the Thirteenth and Fourteenth Courses—500 lbs. Sulphate of Potash, 100 lbs. Sulphate of Soda, and 100 lbs. Sulphate of Magnesia, per acre.

(3) First Course—100 lbs. Pearl-ash, 100 lbs. Bone-ash, 100 lbs. Sulphuric Acid, 100 lbs. Sulphate of Ammonia, 100 lbs. Muriate of Ammonia, and 1000 lbs. Rape-cake; Second Course—300 lbs. Sulphate of Potash, 100 lbs. Sulphate of Soda, 100 lbs. Sulphate of Magnesia, 160 lbs. Bone-ash, 120 lbs. Sulphuric Acid, 100 lbs. Sulphate of Ammonia, 100 lbs. Muriate of Ammonia, and 2000 lbs. Rape-cake; Third, Fourth, Fifth, Sixth, Seventh, Eighth, Ninth, and Tenth Courses—300 lbs. Sulphate of Potash, 200 lbs. Sulphate of Soda, 100 lbs. Sulphate of Magnesia, 200 lbs. Bone-ash, 150 lbs. Sulphuric Acid, 100 lbs. Sulphate of Ammonia, 100 lbs. Muriate of Ammonia, and 2000 lbs. Rape-cake, per acre; Eleventh and Twelfth Courses—the same in other respects as in Courses 3-10, but the Superphosphate contained high percentage mineral phosphates, and containing 37 per cent., or more, of soluble phosphate. For the Swedes of the Thirteenth and Fourteenth Courses—500 lbs. Sulphate of Potash, 100 lbs. Sulphate of Soda, 200 lbs. Sulphate of Magnesia, 600 lbs. Basic Slag, 2000 lbs. Rape-cake, 100 lbs. Sulphate of Ammonia, and 100 lbs. Muriate of Ammonia, per acre.

(4) The quantities given in *Bushels* represent the *Dressed* Corn only.

(5) The "Total Produce" of the Corn-crops includes Dressed Corn, Offal Corn, Straw, and Chaff.

(6) Two cuttings.

[For Summary Table of the above results, see pp. 120-121.]

AGDELL FIELD.

(Area under experiment, about 3 acres.)

EXPERIMENTS ON AN ACTUAL COURSE OF ROTATION—TURNIPS, BARLEY, LEGUMINOUS CROP (OR FALLOW), AND WHEAT.

SUMMARIES OF THE RESULTS GIVEN IN TABLES I, II, III, AND IV. (pp. 112-13, 114-15, 116-17, and 118-19), RESPECTIVELY.

As the Table shows, *averages* are given for each of the four portions of the experimental land, for which Tables I, II, III, and IV, respectively, give the details. The averages are given first of the produce of the eight intermediate Courses (Courses 2-9, 1852-1883); that is, excluding the First Course, when the land was in somewhat uneven condition, and when (as the detailed Tables show), on some portions Norfolk Whites, and on others Swedish Turnips, were grown; excluding also the Tenth, Eleventh, Twelfth, and

1 lb. (pound avoird.) per acre = (about) 1.12 Kilogramme per Hectare, or 0.57 Zollverein Pfund, per Prussian Morgen.
1 cwt. (hundredweight) per acre = (about) 125.5 Kilogrammes per Hectare, or 0.64 Centner per Pr. Morgen.

(1) All the crops were more or less affected by wire-worm, large bare patches appearing on many plots; and much immature and blighted.

(2) Owing doubtless in great part to the imperfect development of the grain from the crop of 1879, much of the wheat crop of 1880 did not germinate at all, and of that which did come up a great deal was afterwards destroyed by wire-worm, so that at the end of March it was a question whether there would be a plant left in the field worth saving. With the thin wheat plants an extraordinary growth of weeds, which the wet month of July much favoured and made it impossible to keep under.

(123)

WHEAT, 12 YEARS, 1871-1882, EACH YEAR IN A DIFFERENT FIELD.

1876; Harpenden Field; 2 cwt. Nitrate Soda; after Mangels (with Dung), 1875, carted off.	1877; Sawpit Field; 1½ cwt. Nitrate Soda; after Mangels (with Dung), 1876, carted off.	1878; Foster's Field; 2 cwt. Nitrate, after White Turnips (with Dung and Artificial), 1877, part Fed, part carted off.	1879; (1) Little Knott- Wood Field; 2 cwt. Nitrate; after Clover. First and second Crops, as Hay; afterwards Fed.	1880; (2) Harpenden Field; 50 bushels of Soot; after Clover unmanured. One Crop as Hay; after- wards Fed.	1881; Rickyard Field; 1½ cwt. Nitrate Soda; after Mangels (with Dung and Guano), 1880, carted off.	1882; (4) Foster's Field; 2 cwt. Nitrate Soda; after Fallow 1881.	(3) Averages, 8 Years, 1871 to 1878 inclusive.	Nos.

wheats appeared to suffer most, either from imperfectly developed seed, wire-worm, or blight. The most satisfactory crop was "Webb's Challenge," the seed for which was obtained direct from the seed-man, not grown on the farm, as were the others.

(3) Owing to the produce of 1879 and 1880 being so exceptionally bad, that of those years is not included in the averages; nor is that of 1881.

(4) The crop of 1882 was completely beaten down by the high winds and heavy rains of July, which greatly interfered with the proper maturation of the grain; the produce was therefore not kept separate or weighed; and in some places not even threshed.
